AMERICAN MEDICAL ASSOCIATION, CHICAGO, 1927

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1927-1928

HEADQUARTERS OF THE ASSOCIATION, 535 N. DEARBORN ST., CHICAGO

GENERAL OFFICERS

PRESIDENT—JABEZ N. JACKSON	Kansas City, Mo.
PRESIDENT-ELECT—WILLIAM S. THAYER	Baltimore
VICE PRESIDENT—CHARLES A. ELLIOTT	Chicago
SECRETARY AND GENERAL MANAGER—OLIN WEST	Chicago
TREASURER—AUSTIN A. HAYDEN	Chicago
SPEAKER, HOUSE OF DELEGATES—F. C. WARNSHUIS	Grand Rapids, Mich.
VICE SPEAKER, HOUSE OF DELEGATES—ALLEN H. BUNCE	Atlanta, Ga.
EDITOR AND GENERAL MANAGER EMERITUS—GEORGE H. SIMMONS	Chicago
EDITOR—MORRIS FISHBEIN	Chicago
BUSINESS MANAGER—WILL C. BRAUN	Chicago

BOARD OF TRUSTEES

J. H. Walsh, Secretary	Chicago, 1928
A. R. Mitchell	Lincoln, Neb., 1928
D. Chester Brown	Danbury, Conn., 1929
E. H. Cary	Dallas, Texas, 1929
Joseph A. Pettit	Portland, Ore., 1930
J. H. J. Upham	Columbus, Ohio, 1930
C. W. Richardson	Washington, D. C., 1931
E. B. Heckel, Chairman	Pittsburgh, 1932
Rock Sleyster	Wauwatosa, Wis., 1932

JUDICIAL COUNCIL

F. W. Cregor	Indianapolis, 1928
M. L. Harris, Chairman	Chicago, 1929
George E. Follansbee	Cleveland, 1930
J. N. Hall	Denver, 1931
Donald Macrae, Jr.	Council Bluffs, Iowa, 1932
Olin West, Secretary, ex officio	Chicago

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Arthur D. Bevan, Chairman	Chicago, 1928
M. W. Ireland	U. S. Army, 1929
Louis B. Wilson	Rochester, Minn., 1930
Walter F. Donaldson	Pittsburgh, 1931
Ray L. Wilbur	Stanford Univ., Calif., 1932
S. W. Welch	Montgomery, Ala., 1933
Emmett P. North	St. Louis, 1934
N. P. Colwell, Secretary	Chicago

COUNCIL ON PHARMACY AND CHEMISTRY

(Standing Committee of Board of Trustees)

R. A. Hatcher	New York, 1928
E. E. Irons	Chicago, 1928
W. T. Longcope	Baltimore, 1928
W. McKim Marriott	St. Louis, 1929
C. W. Edmunds	Ann Arbor, Mich., 1929
Treat B. Johnson	New Haven, Conn., 1929
Morris Fishbein	Chicago, 1930
G. W. McCoy	Washington, D. C., 1930
F. G. Novy	Ann Arbor, Mich., 1930
George H. Simmons	Chicago, 1930
L. G. Rowntree	Rochester, Minn., 1931
Torald Sollmann	Cleveland, 1931
Lafayette B. Mendel	New Haven, Conn., 1931
Reid Hunt, Chairman	Boston, 1932
W. W. Palmer	New York, 1932
A. J. Carlson	Chicago, 1932
W. A. Puckner, Secretary	Chicago

COUNCIL ON PHYSICAL THERAPY

(Standing Committee of Board of Trustees)

W. T. Bovie	Chicago
Arthur Compton	Chicago
Ralph Pemberton	Philadelphia
Harry E. Mock	Chicago
W. E. Garrey	Nashville, Tenn.
A. S. Warthin	Ann Arbor
Francis Carter Wood	New York
A. U. Desjardins	Rochester, Minn.
George Miller MacKee	New York
H. B. Williams	New York
F. B. Granger	Boston
Olin West, ex officio	Chicago
Morris Fishbein, ex officio	Chicago
H. J. Holmquest, Executive Secretary	Chicago

COUNCIL ON SCIENTIFIC ASSEMBLY

Roger S. Morris	Cincinnati, 1928
F. P. Gengenbach	Denver, 1929
J. Shelton Horsley, Chm.	Richmond, Va., 1930
John E. Lane	New Haven, Conn., 1931
Frank H. Lahey	Boston, 1932

AND EX OFFICIO

The President-Elect, the Editor and the Secretary of the Association.

COMMITTEE ON SCIENTIFIC EXHIBIT

D. Chester Brown, Chairman	Danbury, Conn.
Rock Sleyster	Wauwatosa, Wis.
J. H. J. Upham	Columbus, Ohio

ADVISORY COMMITTEE

George Blumer	New Haven, Conn.
Paul J. Hanzlik	San Francisco
Ludvig Hektoen	Chicago
Urban Maes	New Orleans
Hans Zinsser	Boston
Ralph H. Major	Kansas City, Kan.
J. Shelton Horsley, ex officio	Richmond, Va.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

W. C. Woodward, Executive Secretary - Chicago

BUREAU OF HEALTH AND PUBLIC INSTRUCTION

J. M. Dodson, Executive Secretary - - Chicago

BUREAU OF INVESTIGATION

A. J. Cramp, Director - - - - - - Chicago

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, James E. Paullin, Jr., Atlanta, Ga.; Vice Chairman, William H. Robey, Boston; Secretary, Bryce W. Fontaine, First National Bank Building, Memphis, Tenn.

SURGERY, GENERAL AND ABDOMINAL—Chairman, J. Shelton Horsley, Richmond, Va.; Vice Chairman, Harold Brunn, San Francisco; Secretary, Frank H. Lahey, 605 Commonwealth Avenue, Boston.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY—Chairman, J. C. Litzenberg, Minneapolis; Vice Chairman, Edward Speidel, Louisville, Ky.; Secretary, Carl Henry Davis, 518 Goldsmith Building, Milwaukee.

OPHTHALMOLOGY—Chairman, Walter B. Lancaster, Boston; Vice Chairman, Edmond E. Blaauw, Buffalo, N. Y.; Secretary, William C. Finnoff, Imperial Building, Denver.

LARYNGOLOGY, OTOLOGY AND RHINOLOGY — Chairman, Frank R. Spencer, Boulder, Colo.; Vice Chairman, H. Marshall Taylor, Jacksonville, Fla.; Secretary, William V. Mullin, Cleveland Clinic, Cleveland.

DISEASES OF CHILDREN—Chairman, Hugh McCulloch, St. Louis; Vice Chairman, Rood Taylor, Minneapolis; Secretary, C. A. Aldrich, 545 Lincoln Avenue, Winnetka, Ill.

PHARMACOLOGY AND THERAPEUTICS — Chairman, Roger I. Lee, Boston; Vice Chairman, Norman M. Keith, Rochester, Minn.; Secretary, Robert L. Levy, 31 East 72d Street, New York.

PATHOLOGY AND PHYSIOLOGY—Chairman, H. R. Wahl, Kansas City, Mo.; Vice Chairman, M. H. Rees, Denver; Secretary, Josiah J. Moore, 5 South Wabash Avenue, Chicago.

NERVOUS AND MENTAL DISEASES — Chairman, Lewis J. Pollock, Chicago; Vice Chairman, John L. Eckel, Buffalo, N. Y.; Secretary, Walter Freeman, 1801 Eye Street, N. W., Washington, D. C.

DERMATOLOGY AND SYPHILOLOGY—Chairman, Udo J. Wile, Ann Arbor, Mich.; Vice Chairman, Samuel Sweitzer, Minneapolis; Secretary, William H. Guy, Jenkins Arcade, Pittsburgh.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH—Chairman, Louis I. Harris, New York; Vice Chairman, C. N. Leach, Montgomery, Ala.; Secretary, E. L. Bishop, Memorial Building, Nashville, Tenn.

UROLOGY—Chairman, Frank Hinman, San Francisco; Vice Chairman, R. Arthur Hooe, Washington, D. C.; Secretary, Hermon C. Bumpus, Jr., Mayo Clinic, Rochester, Minn.

ORTHOPEDIC SURGERY—Chairman, James Archer O'Reilly, St. Louis; Vice Chairman, Walter G. Stern, Cleveland; Secretary, H. W. Meyerding, Mayo Clinic, Rochester, Minn.

GASTRO-ENTEROLOGY AND PROCTOLOGY—Chairman, Joseph Sailer, [illegible] rman, Alois B. [illegible] Secretar [illegible] Mayo Clinic, [illegible]

RADIOLOGY—Chairman, Edward H. Skinner, Kansas City, Mo.; Vice Chairman, Charles A. Waters, Baltimore; Secretary, Fred M. Hodges, 1000 W. Franklin Street, Richmond, Va.

THE RELATIONS OF THE PHYSICIAN TO PUBLIC HEALTH

FROM THE STANDPOINT OF THE PHYSICIAN IN THE SMALL CITY *

ARTHUR T. HOLBROOK, M.D.
MILWAUKEE

The cardinal sin in medical discussion is to wander from the topic. My topic is traversed by so many trails and crossroads that it becomes quite necessary at the outset to determine those conditions of public health control and medical practice in the small city which are essentially different from those of larger or smaller organized communities.

It is perfectly clear that all physicians should take an interest in public health—that would be ideal; but the conditions before us are real and not ideal. It also seems clear that the real attitude of the profession is that the interest of the practicing physician in the administration of public health is of far less importance in the large cities than it is in the rural communities. In the large cities the matter is in the hands of full-time, well paid, presumably competent health officers with an ample staff of assistants, while the unofficial public health agencies are well organized, well financed, and directed for the most part by expert officers and workers. In the rural community too often the part-time, underpaid, inexperienced health officer has no resources, personal or acquired, with which to meet his problem and usually does not receive any assistance from unofficial organizations. The interest and aid of the physicians in this community are imperatively demanded, whereas in the large city the practicing physician realizes that the public health affairs are in competent hands and does not feel any particular urge to interest himself or to assist, outside of a conformity with the laws and rules.

The interest of the average physician, therefore, may be stated as varying inversely as the number of people in his community; and somewhere in this scale comes the district, town or city that concerns each individual physician. What, then, are the conditions peculiar to the smaller city designated as my topic?

Such a city has gone past the stage where the personal attention of the public health officials to individual cases and minor problems is demanded, and yet is in the stage where the officials have a personal knowledge of the city's physical condition, housing conditions, the various factors entering into individual health problems; not a knowledge by report or by hearsay but by personal contacts. Furthermore, the health officer of such a city has a personal acquaintance with perhaps a majority of its physicians and knows by reputation most of those he has not met. He is expected by the profession to do more than mere executive directing. Although it is not demanded of him, it is no unusual experience for the health officer to take up directly with physicians or families specific problems of quarantine, garbage disposal, odor nuisances and the like. Because of the personal relation he prefers not to delegate the duty. He knows the family concerned either personally or by reputation; he knows where it lives and the conditions of the neighborhood; he probably knows the physician in the case and calls him by his first name.

A comparable condition exists between the physicians of the smaller city and the unofficial public health organizations.

The average physician of such a city knows personally and perhaps intimately some of the officers, workers and members of the Red Cross, family welfare, antituberculosis and practically every such local organization. He is consulted by the members concerning their problems; he feels at liberty to make suggestions to his friend, who is a director of the society. He attends some of the annual dinners, contributes a moderate sum, and may be on one or two committees.

Without doubt there are many medical conditions affecting our topic peculiar to these communities, but in my opinion the outstanding, distinguishing characteristic is in the *personal contact*. In the larger city the health department and allied organizations are probably maintained at a higher development, but the personal touch is lost. In the smaller community the personal relation is even closer, but the health department and the organizations are missing. The small city combines the two.

Granting this personal contact to be an important element, what advantage can be taken of it in developing the most satisfactory relationship between the small city practitioner and the agencies for public health?

In the first place, if a hundred private practitioners in my community were to pick up a journal containing an article with the title of this paper, at least eighty-five of them would pass it by. Of the other fifteen there would be eight who consistently read journals from cover to cover, and the other seven would include the specially trained public health physicians, the men who have a grievance against public health agencies and are looking for more arguments, and the man who has been asked to write a paper on the subject. This fairly expresses the interest of the profession in a small city, and the general lack of a feeling of personal responsibility to problems of public health.

I wish to make clear my belief that practically every ethical practitioner in every department of medicine recognizes the importance of public health control through agencies both official and unofficial. No body of professional or nonprofessional men of which I have knowledge has shown the unselfish, altruistic support of any program for public welfare that has characterized the efforts of our profession to safeguard the public health. Nevertheless, I am certain that under our present conditions the vast majority of private practitioners feel that the actual responsibility for the carrying out of this program rests with those who have chosen to specialize in this branch, those who volunteer for such service, and particularly those who are selected as officials and are paid to do the job. Each of the eighty-five would argue earnestly in favor of the program. He signs birth and death certificates punctiliously; he reports communicable diseases scrupulously; he favors milk inspection, increased taxes to insure better sewage disposal, and all the rest of that long list of needs so familiar to those who read health reports. Over the cigars after dinner he enthusiastically explains how the health department has cut down typhoid so that he has not seen a case in two years, whereas twenty years ago he thought his practice was falling off if he had less than a half-dozen cases on hand. He believes in it heart and soul; but he doesn't study it; he doesn't attend public hearings on questions affecting the city's health; he joins some of the allied societies, but he doesn't attend the meetings; he favors public clinics, but he couldn't tell where they are located. He is something like the Christian who never goes to church.

---

* Read before the Conference on Public Health, Chicago, March 24, 1927.

He certainly furnishes a tempting morsel of food for the thought of public health workers. How is this man to be sold the idea that every practitioner of medicine who is granted a license has a definite obligation to the state and that it is nothing short of duty for him actively to assist in the work of the health department? If he chances to live in New York State, the law and the sanitary code of his state specifically point out to him this duty and the penalties for evading the duty.

He perhaps is one of those who believe in a definite line between preventive and curative medicine. Possibly without giving it much analytic thought he takes the attitude that his job is to take care of people after they are sick, and that it is the concern of the health department and volunteer organizations to formulate regulations and enforce measures for the prevention of disease. He certainly is on thin ice. If he were a surgeon where would he draw the line between the prevention and cure of tetanus, anthrax, erysipelas, or of many other types of infection that have surgical aspects? If he were a laryngologist, what about diphtheria, toxin-antitoxin, control of carriers? If a pediatrician, how about the milk supply, prenatal management, the handling of a poliomyelitis outbreak, the Dick procedures? Each specialty would readily present its proof that no department of practice can definitely separate preventive from curative medicine. With the importance of quarantine, of surveys in limiting infections, the use of laboratory methods in diagnosis and control of therapeutic measures, the use of vaccines and serums, the resources presented by the public health department and allied organizations for the intelligent use and aid of practicing physicians, it is quite difficult to see how any thinking man would attempt to segregate preventive and curative medicine and lose the benefits of the cooperation of the two branches.

Among these eighty-five men there will be surely found a definite type of successful practitioner. He does consistently good work and he is well paid. His days are filled from early to late. He works in a little time for studying cases and for journals and meetings. He squeezes in an occasional nine holes of golf and a few rubbers of bridge. He has not had a vacation in three years. How in heaven's name, he demands, can he be expected to attend public health meetings, join the Infant's Welfare Club, read *Hygeia,* and let his assistant put in two hours at the county dispensary every Tuesday and Friday—a couple of his busiest days. He is perfectly willing to pay his taxes and help hire the best specialists possible for the job, but he certainly has not the time for any such "outside" work as public health.

Now, this sort of man is the very one needed in public health work. He is very sure to be well prepared, he is a so-called live wire, he can do things and understand people. He has to be convinced that if all the men like him should refuse an active participation, the health program of our smaller city would fail.

Also in this eighty-five will be another distinct type. He is the man who is an ultraspecialist, puts in all his spare time on an arbeit, and harbors the impression that on the upper rounds of the medical ladder are poised those who are doing research work, while down below in an indefinite somewhere are the physicians who are taking care of sick people or trying by practical means to prevent sickness. He would feel that public health matters should be entirely in the hands of those who have made an exclusive study of the subject and that it is not a matter for his concern. Honor to the microbe hunters, the laboratory problem workers. Grateful are the acknowledgments to them for the weapons and ammunition they place in the armamentarium of the health workers. But equal honor, at least, to the earnest, studious, ethical men who are working to prevent and cure sickness. A good salesman is needed to tell a thing or two to this hyperdeveloped man.

The unsuccessful man may be in the eighty-five or in the fifteen. Usually he does not matter so much, for he lacks preparation, or force, or common sense or industry. Possibly—and probably—he has a grievance against the health department and the volunteer organization. They vaccinate his patients free; they take his baby to the welfare meeting and have its food prescribed; the clinics and dispensaries get many of the people in his neighborhood and he just plainly has no show. Well, this man in many communities probably has a right to complain. In the zeal to build up dispensaries and clinics; to better conditions of motherhood, infant care and feeding; to stamp out tuberculosis, and other laudable enterprises, the case of this struggling doctor in a poor neighborhood may be overlooked. It is an old, old controversy and no matter how long or how loud it is argued it will always come back to the one common sense conclusion of recognizing on the one hand the absolute need of free clinics and dispensaries, and on the other hand the absolute requirements that they be carefully regulated and supervised so as not to work an injustice to the physician who could not survive if the government or volunteer organizations indiscriminately offered free treatment to those who should pay. Fairness, tact, a mutual understanding and common sense are the remedies.

There are probably a few men who snapped back the page on public health matters with some show of feeling. They are the ones who rarely lose an opportunity to warn of the perils of state paternalism and the regulation of one's private affairs by commissions and societies, by long haired men and short haired women and other cranks, who feel that they have a mission to save the world. One of these physicians tells of the nurse who came from the welfare society to show one of his patients how to make her bed and wash her baby. He deplores the circumstance that he was not there to throw the nurse out the window. Another knows of two women in the motherhood association who are not fit to be in the same theater with his scrub woman, and he has heard that the treasurer of the Red Cross chapter beats his wife. It is an easy thing to let personalities influence one's estimation of a movement or an organization with which these personalities are associated. Let a popular, highly esteemed and trusted man head an organization, and success and achievement are fairly certain to follow. On the contrary, a weak president or an uninterested, carelessly chosen board may ruin for a time any organization. It becomes important, therefore, for these groups not to organize loosely or carelessly and stand vulnerable to opponents who are only too ready to wreck what may be a splendidly conceived movement for great public good.

In my opinion the medical profession leaves the work of the allied organizations too much in the hands of the laity. Some one has said that "medicine has a poor vision when it comes to seeing socially," and the indictment is more or less true. There would be far less criticism to offer these organizations if physicians were a bit more far-seeing, if they sought membership and activity in these agencies, gave freely of expert medical advice, interpreted and explained technical aspects to lay members, gave talks before clubs and other groups to help educate the public in the objects and activities of antituberculosis, Red Cross, family and infant welfare and like activities. On their side these organizations should realize that their greatest usefulness is attained when they supplement the work of the public health authorities and work in close cooperation with them. Kipling's oft-quoted lines might well be made familiar to their membership: "It ain't the individual nor the army as a whole, but the everlasting team-work of every bloomin' soul."

So far I have been considering chiefly what the public health agencies should expect of the physician. Let us shift the point of view and ask what the physician of a small city has a right to expect of his public health department.

First of all, the head of the health department in a small city must be a scientifically trained man, adequately prepared for his job. Too often these requirements are subordinated to the political qualifications that influence his appointment. I quote the statement of a recent report that "the greatest handicap to municipal health work in Illinois arises from the harmful influence of local partisan politics;" and if department heads are politicians instead of single-purposed, scientific workers the health of the public is going to suffer. In the selection of this trained official, for a smaller city at least, I feel strongly that he would be a far more efficient public servant if he were a local man rather than an imported stranger. I can conceive of local situations which would demand the seeking of an outsider for the health officer, but this would be a distinct disadvantage in losing the personal contact and acquaintanceship which I have urged as an important asset.

The physicians have a right to know definitely the attitude of the health officer toward medical practice in the community. Is he going to insist on protection of the rights of physicians in the dispensaries and clinics, on the courteous cooperation in the public city hospitals, on the proper reference of cases back to the original attending physician? I myself have never met a public health officer who, if approached in a reasonable spirit, was not perfectly willing to cooperate with me in all fairness in the consideration of my patient. Probably the other sort of health officer exists, but he is not an avis vulgaris and he would be very short-sighted not to realize that without cordial relations with the medical profession he is doomed to absolute failure, no matter how highly trained he may be.

In the smaller city the fact of a severe or unusual illness is general news or gossip and is given daily newspaper notice. It becomes a matter of no small importance to the physician to keep his conducting of the case free of criticism. If he has a clash with health officers about quarantine, removal to hospital, attendance in school of exposed children, or similar situations, and is openly and tactlessly opposed by the health department, he is very liable to unfair criticism and to being discredited by a large number of people. Consideration, tolerance and tact on both sides are all that is needed.

The advent of quacks and irregular practitioners in a small city presents its special problem. Contrary to conditions in a larger city, through hearsay and the newspaper practically the whole population of the smaller city knows of the presence of the impostors and prompt dealing with them and deportation become necessary to the medical morale of the community. This is a task the ethical physicians have a right to demand of the health department.

It would be tiresome to continue the list of the many situations affecting the relations of small city public health workers and practicing physicians. Enough has been said to indicate some of the more important problems, and I should like to recapitulate and emphasize three of them.

1. *The personal element in the relationship.* This means the selection of a properly qualified, local man at the head of the health department; the stimulation of interest in official and unofficial public health work on the part of practitioners and laymen; the cooperation of these men; the taking advantage of personal acquaintanceship with conditions and people in establishing a mutual, cordial and efficient relationship.

2. *The groundless fear that the public health administration will deprive deserving physicians of a competent livelihood.* This is a matter which simple fair-mindedness and common sense will settle among men who have a disinterested desire to cooperate.

3. *The fallacy of trying to define the exact and separate responsibilities of preventive and curative medicine.* There is no line of cleavage between these two. Of necessity they overlap, and where they run together each department must cooperate with the other. When the field of each becomes distinct, there the individual responsibility of each begins.

CONCLUSION

What measure or measures can be offered to secure most satisfactorily a proper handling of these three important considerations? I believe that Dr. John P. Koehler, health officer of my city of Milwaukee, has devised an effective means to the end we are seeking in the appointment of his advisory board. I am aware that the appointment of advisory boards and committees is not new, and have no doubt that other health officers have appointed boards along similar lines; but I do know that Dr. Koehler's plan has been particularly carefully studied and carried out and that there are small cities where such an advisory board is not being used although it would form a valuable adjunct.

The advisory board of the Milwaukee health department is composed of fourteen members. It includes six physicians and eight laymen. The physicians are appointed as representatives of the leading local medical societies, include the head of the milk commission, and are well distributed among the staffs of different hospitals, forming a group that is comprehensive of the various medical specialties and interests. The laymen include representatives from the allied volunteer health and social organizations, chairmen of the federated trades council, building trades union, etc., and the chairmen of the health committees of the county and city councils.

The health officer presides over and directs the activities of the board. When a question of general interest is before the health department, the entire board is asked to attend meetings for its consideration. It is definitely understood by the health officer and the members of the board that any member or group of members is subject to call and to consultation by the department on problems of which such members may have particular knowledge.

The results of such an arrangement are manifold. The health officer is able to avail himself of the advice of experts. The various interests represented by the board have a ready means of intelligent, practical appeal to the health authorities. Mooted questions after discussion at the general meeting may be carried by individual members to the organizations they represent, and the sense of these groups be carried back to help the satisfactory decision of the board.

When some important measure is before the common council, the county supervisors, the state legislature, the mayor or the governor, a great deal of influence will be carried with the expression of opinion of the fourteen men who have been chosen because of recognized qualifications and who represent the opinions of hundreds of other citizens composing the organizations from which they are delegated. In the small city where these men are personally and presumably favorably known, such influence is very potent, and the effect of the newspaper published personnel of such a board with their expressed opinions is of much importance in stimulating that active public interest on which the health of every city must largely depend. The cooperation of the medical profession and the volunteer health agencies with the health department, and the mutual confidence inspired by this intimate contact of lay interests and medical interests have earned for this board of advisers the title it has been given of the "Unofficial Guardian of the City's Health."

711 Goldsmith Building.

Auricular Flutter.—A study of auricular flutter throws further light on the occurrence of syncopal attacks associated with tachycardia. An attack of auricular flutter can be distinguished in many cases from one of paroxysmal tachycardia only by means of an electrocardiographic record. It is characterized by a very rapid ventricular rate, reaching sometimes from 200 to 220 beats per minute or even, according to some, 300. As a result the ventricular contractions at the onset may be so weak that the patient loses consciousness. An attack of auricular flutter may be sudden, brief, without any previous symptoms of ill health, and without any subsequent change in the heart.—Sutherland, G. A.: Fits and Faints, *Lancet,* June 11, 1927.

THE RELATIONS OF THE PHYSICIAN TO PUBLIC HEALTH *

HUGH S. CUMMING, M.D.
Surgeon General, U. S. Public Health Service
WASHINGTON, D. C.

I have been asked as Surgeon General of the federal Public Health Service and as representing the official health organizations of the country to discuss "The Relations of the Physician to Public Health." It is needless to say that any views I may present are only my own personal impressions, which may perhaps be of value because of the opportunities that have been afforded me by my official position during the past seven years and through a service of thirty-three years in different regions of our country to hear the opinions not only of public health officials but also of nonofficial workers, medical men in private practice, and the public in whose welfare we are all equally concerned.

As a matter of fact there is probably no unanimity of opinion throughout the profession; and, indeed, there must be so many varying factors, both personal and environmental, throughout the country which affect individual opinion that there never will be any "cast iron" written constitutional delimitations of rights and responsibilities applicable to the whole country. If the purpose of this conference be to lay down such rules we shall fail, for in the last analysis the answer lies not in us but in the public whom we serve.

Nevertheless, there have been few conferences in this country more fraught with the possibilities of good or evil to the medical profession and to the welfare of the public than this may prove to be, and I feel very deeply that in the beautiful language of the Common Prayer Book, "It is not by any to be entered into unadvisedly or lightly but reverently, discreetly, advisedly, soberly, and in the fear of God."

May I not quote Sir William Osler's beautiful description of our profession as something to think about in the conference?

> 'Tis no idle challenge which we physicians throw out to the world when we claim that our mission is of the highest and of the noblest kind, not alone in curing disease but in educating the people in the laws of health, and in preventing the spread of plagues and pestilences, nor can it be gainsaid that of late years our record as a body has been more encouraging in its practical results than those of the other learned professions. Not that we have lived up to the highest ideals—far from it—we are only men. But we have ideals, which means much, and they are realizable, which means more. Of course, there are Gehazis among us who serve for shekels, whose ears hear only the lowing of the oxen and the jingling of the guineas, but these are exceptions; the rank and file labor earnestly for your good, and self sacrificing devotion to your interests animates our best work.

We know as a biologic fact that the instinct of perpetuation of the species is far more powerful than self preservation, and in our profession the preservation and betterment of our fellow man is far more potent than our own interests, as has been and is being shown by every physician worthy of the cause. I am confident that we approach the problem in this spirit of self abnegation.

---

* Read before the Conference on Public Health, Chicago, March 24, 1927.

PAST AND PRESENT RELATIONSHIP OF PUBLIC HEALTH AND MEDICAL PROFESSION

From the earliest civilization there has been an almost uninterrupted recognition of the fact that public health is a governmental or public function, as has been evidenced by the public water-works and baths and various official positions established by Greek, Roman, and other governments, the maritime quarantine laws, segregation of lepers, the Hebrew and Egyptian laws regulating hygiene, and the English laws about plague.

There would seem, too, to have been some provision for hospitalization, such as the temples of Æsculapius and the Roman hot baths at Sospel in Gaul and at Bath in Britain, to which soldiers were sent for cure and convalescence.

It is difficult to distinguish between ecclesiastical and secular government in the middle ages, but there gradually developed orders and institutions for the care of the sick, and the endowments of such institutions may be properly considered as the beginning of nonofficial public health work.

But such effort was for the relief of suffering rather than its prevention, except in the segregation of lepers and other quarantine procedures against the epidemic diseases.

Nor can the lack of preventive medical measures be justly attributed to indifference on the part of rulers and peoples, for "man power" was the essential factor of success in those days; rather was it due to ignorance as to what to do.

The modern public health movement, by which I mean action taken by organizations official or nonofficial to prevent the spread of disease and to remove or alleviate conditions both personal or environmental so as to eliminate diseases from masses of people as distinguished from treatment of the individual, began in Great Britain in the nineteenth century as a result of the industrial development, and doubtless for the same reason about the same time as movements toward better housing and sanitation. It has been a governmental function there from the start, and I do not think nonofficial bodies have had a great influence other than educational.

Britain, however, is a compact, thickly populated area, and laws regulating sanitation problems such as housing; pollution of streams and quarantine restrictions became a matter of necessity about the middle of the nineteenth century.

In this country, until the past quarter of a century, and with the exception of the two or three industrial states and a few large cities, our problems in preventive medicine were essentially those of environment, such as the suppression of pestilential diseases and the control of water and milk supplies, which are matters for governmental control.

Our development has not been one of a central government gradually decentralizing and giving up powers to state or local authority but, on the contrary, the colonies, subsequently states, retained and developed their public health powers as need required, while federal authority was restricted to assisting the states and to matters of foreign and interstate commerce, and grew *pari passu* with the development of the latter.

Even within the states the growth of health organizations was local and urban rather than state wide save in states subject to invasion from yellow fever. This condition continued with the exception of a few urban or state organizations until within the memory of many of us here. We must remember that until within the past thirty-odd years specific remedies were known for only malaria and syphilis, while the methods of transmission of the great pestilences were unknown except those spread by contact.

Modern public health activities were made possible by and followed the epochal discoveries of the bacterial causation and mode of transmission of such diseases as tuberculosis, cholera, diphtheria and typhoid fever, by Pasteur, Koch and others, and were in a few years broadened by the discovery of diphtheria and other antitoxins followed rapidly by the discovery by Manson and others of the rôle of insects and vermin. Within two decades more knowledge had been gained in medical science than in all the ages before.

While the effect of this knowledge on the field of curative medicine was revolutionary, it was insignificant compared with the events that followed in the great field of preventive medicine. As the searchlight of science was thrown into the misty darkness of one after another of the pestilential diseases which had for ages been scourging the human race, the hopeless and futile blind efforts of the past gave way to intelligent labor for their conquest.

The army of physicians who had hitherto stood alone in its fight against disease was joined by allies such as the sanitary engineer, the laboratory scientist and others.

And now that the trumpet of battle gave no uncertain sound and the physician could speak to the public in language which could be understood, as St. Paul put it, the people of intelligence began to be aroused to the importance of the application of knowledge to the prevention of disease, and there followed the installation of water supplies and milk control with rapid lessening or disappearance of the water-borne diseases such as typhoid fever and cholera.

Application of appropriate measures led, too, to the practical elimination of typhus fever and diminution of tuberculosis and smallpox.

It should be recalled that quite naturally attention and effort were directed against the great epidemic diseases, such as cholera, yellow fever and typhoid, against which individual action was of little avail and in which governmental action was necessary.

In this field the rôle of the physician in private practice can consist only in his wise guidance of the opinions of his fellow citizens in securing adequate public health organization in his community, state and county, and in the correst diagnosis and faithful reporting of disease. His responsibility here is great and even now is too often shirked, not always because of ignorance or selfishness but because of mistaken notions of professional ethics and dislike of political activity.

DEVELOPMENT OF HEALTH ORGANIZATIONS

No review of the growth of public health activity in this country would be complete without reference to the development, unique and almost peculiar to this country, to a much less extent in Great Britain, of national nonofficial organizations devoted to various phases of improvement of the people from general welfare or education, to fighting individual diseases. The influence of these organizations on the public health has been of inestimable value not only in the work accomplished by them but also in their influence on public opinion and stimulation of government, legislative and executive, to increased efficiency.

Sixty years ago there was, so far as I know, no large endowment nation-wide in its scope.

Mr. Peabody gave the endowment for the Southern Educational Board, and if it had done nothing else than bring Wickliffe Rose into the field of welfare and public health it would have been money well spent. I am informed that now the endowments for educational purposes aggregate the stupendous sum of one billion of dollars, and it should be remembered that much of this is being used to educate physicians for private practice.

Sane education, even if not consciously directed toward that end, is a powerful factor in the betterment of public health.

In addition there have been created organizations devoted entirely or in part to public health work, some of which depend entirely on endowments, such, for instance, as the Rockefeller Foundation, the Commonwealth Fund and the Milbank Fund, while others, such as the National Tuberculosis Association and American Social Hygiene Association, depend wholly or in part on voluntary subscription.

The efforts of these organizations have been directed along quite different though sometimes converging lines, for while the Rockefeller funds for instance have been expended directly in educating physicians in research and in directly aiding state and local officials, other organizations which depend on popular subscriptions must of necessity concentrate on those problems in public health which interest the lay public and in the solution of which nonprofessional personnel can actively engage. They must also be directed chiefly toward efforts which rapidly show tangible results. Perhaps the greatest influence of such organizations has been in the education of the public and the stimulation of governmental activity.

However much we may believe in the doctrine laid down by Disraeli and other statesmen, both British and American, that the protection of the health of the people is the first duty of a statesman and that public health is a governmental function, it is not probable that, under the present conception of government, we shall either eliminate nonofficial organizations or prevent the formation of others. We have no idea, I think, in this country of having confiscatory tax rates which will automatically dissolve fortunes on the death of their makers. We have not in this country anything like hereditary titles or honors. So long as human nature remains as it is, large fortunes will be left for the endowment of organizations for the promotion of public health. When they are not contrary to the public interest, an attempt must be made by the trustees of such funds to carry out the desire of the donor. I am frank to say I believe there are too many nonofficial societies, national in scope, in the country. I am sure you will agree with me that many nonofficial as well as official crusades have been unwise and indeed perhaps harmful; but there is a marked tendency toward consolidation, cooperation and the employment of enlightened methods.

DEVELOPMENT OF MEDICAL PROFESSION

During this same period the medical profession has been passing through a process of evolution from a scattered number of men, individualistic perhaps, to a greater degree than members of any other profession, and with educational qualifications ranging from a mere smattering knowledge of medicine to the highest scholastic attainments and skill. The profession is now perhaps the best organized guild in our country, with organizations from the county and city to the American Medical Association and other special societies. A marked improvement in professional attainments has resulted.

The public has recognized the dignity and importance to the common weal of properly qualified physicians, and has thrown around the permission to practice barriers which require higher intellectual and educational requirements than those of any other calling, including law, the church or nonmedical public service. While the practitioner of former days required little armamentarium beside half a dozen books, a few drugs, and instruments, he now requires an expensive equipment and the assistance of a large staff of technicians. The increased knowledge of disease, too, is such that its possession and application is beyond the capacity of any individual, so that cooperation is necessary.

Although the amount of honorarium has by no means increased in proportion to the increased outlay of the physician in attaining and maintaining his position, it is nevertheless such that concededly the best professional services, even where available, are beyond the financial ability of a very large proportion of our public; furthermore, these requirements are not everywhere available, especially in our rural and small town areas. Nor has the medical profession as such appreciated its duty to the public in the matter of education in preventive medicine.

PUBLIC HEALTH ACTIVITIES

Some of us at least are familiar with the development of urban, state and federal public health activities. Federal medical activities are confined, so far as the Public Health Service is concerned, to treatment of seamen of its several services, and of its personnel injured in line of duty, together with such functions as quarantine and immigration, assistance to the states, and the control of biologic products.

The Veterans' Bureau under existing law, imposing on it the hospitalization of any veteran of any war suffering from any disease regardless of origin, has a responsibility for about four or five million people; a very serious essay at "state medicine" hitherto not attempted in our states.

Our state and health organizations have developed from mere skeleton groups of part-time physicians whose sole object (with one or two exceptions) was the prevention or suppression of epidemics, to highly organized departments whose energy is directed not only toward the elimination or eradication of environmental diseases such as yellow fever, typhoid or malaria, and to the suppression of outbreaks of such communicable diseases as smallpox and diphtheria by isolation and treatment, but who have entered the field of preventive medicine by attempts at universal vaccination and protection against these diseases. Some states have begun the free examination of specimens as well as the manufacture of laboratory products. In several states, free clinics in connection with school work or otherwise are being conducted.

In addition, in many states so-called demonstrations are being conducted and managed by nonofficial organizations.

City health organizations vary from mere attempts at control of communicable disease and of water and milk supplies to frank attempts to enter all fields of preventive and curative medicine which will benefit the public health.

To sum up, the problem which we are discussing would seem to involve the "eternal triangle," the public, the health official, and the practicing physician, unless indeed it is looked on as a quadrangular affair by dividing the health workers into official and nonofficial. The medical profession is more highly organized, and its individuals are more competent than ever before. Its distribution, however, is unequal; and while both personnel and equipment are available to the richer and poorer class in our larger urban communities, it is the general opinion that the full resources of medical sciences are not available to the great middle class in our cities, unless they accept public aid, while in large regions of our country there is insufficient number of physicians and facilities. It is, too, I believe, a fair statement to say that the physicians as a class have not appreciated their obligation to the public in matters of public health, particularly in matters of health education. It is extremely gratifying to know that under President Phillips and the present board of trustees of the American Medical Association this condition is being remedied

Secondly, public health officials and nonofficial organizations devoted to public health no longer have their attention and knowledge concentrated solely or to a large part on the environmental and epidemic diseases, but are directing their energies not only toward the prevention of those diseases which are influenced chiefly by personal hygiene and economic conditions, but also toward procedures that will result not alone in preventing disease but in improving the mental and physical efficiency of the individuals that compose our people. As to the public at large, while those of us whose lives are devoted to public health work are often discouraged by the ignorance and indifference of the public, it is nevertheless true that within the last few years, by the mobilization for the war and by intensive educational efforts, the public as a whole has been aroused to the importance of health. One of the most significant factors is that the question is no longer approached solely from ethical and humanitarian motives, but the enormous economic loss which may be prevented by the application of medical science is now appreciated by great corporations. It is significant that perhaps a larger part of the nonmedical public health work now being done is under the direction of nonmedical men.

Finally, the question of the proper relation of the physician to public health is one that cannot be laid down for the country as a whole. The public cannot be expected to care particularly as to whether the fortunes of the medical profession will be injured in the attainment of the goal of public health. If the profession is not aroused to the importance of the problem and does not wisely guide and assist the public, undoubtedly we shall have, at least in parts of our country, attempts at the socialization of medicine such as are being made in other countries. The physician has been given a privileged status by the state and therefore owes to the public the duties not only of an ordinary citizen but in addition those of an adviser and guide. The answer is not to be sought in any formal action by national organizations. It is to be found in the attitude of the local profession in each community. The duty of the physician to the public should be taught in our medical schools. The local societies should see that public health office is taken out of partisan politics, that competent public health officials are chosen, that adequate appropriations are made available for legitimate public health work, and that moral and active assistance should be given the local officials. It may be significant that in my own life as a public health official I do not recall ever having heard a health officer complain of the intrusion of the private practitioner in his field of activity. I believe that the apprehension of many of the private practitioners as to the possible disastrous effect on their practice of the public health activity is unfounded. It is well to recall the apprehension of the mill workers of England as to the effect of the introduction of machinery on their chances of making a livelihood. We are constantly seeing that as certain fields of medicine are covered by the state, new fields of activity and usefulness are being opened to the medical profession.

In discussing the relationship of the physician to public health, we must appreciate the truth of Lowell's couplet:

New occasions teach new duties,
Time makes ancient truths uncouth.

The science of medicine, including, as it does, the whole field of knowledge, can no longer be restricted within the confines of the medical profession; the biochemist, the sociologist, the physicist, the sanitary engineer and the worker in pure science must necessarily all be included in public health and, from a research standpoint, with curative medicine itself, if indeed there be a line of demarcation between curative and preventive medicine; for instance, the cure and prevention of tuberculosis is as much an economic problem as it is a medical problem. Even in the field of private practice in curative medicine, the physician, in the usual sense of the definition of the term, is often no longer capable alone of diagnosing and treating the patient, but must of necessity rely on nonmedical technical assistants, and ultimately depend for his remedies either on the state or on commercial enterprise under state supervision. The age of the individual craftsman is over. The soldier, whether he fights the battles of science or of war, no longer forges his own weapons. The common note of the present age is cooperation, nor in a political government such as ours can we speak of voluntary and official action as being separate, for the action of the official is the expression of the wish of the people.

CONCLUSION

I am afraid these remarks of mine have been discursive. I am attempting to point out that:

1. It will be impossible for this or any other group to delimit the respective fields of the private practitioner and the public health official in specific terms appropriate to the whole country.

2. The people as a whole appreciate the value of and, in a large part, the method for obtaining health. They are naturally more or less indifferent as to how this end shall be accomplished.

3. The medical profession must appreciate this fact and aid in working out a solution.

4. It is the privilege of the profession to cooperate with the public and its duly appointed representatives in the development of a satisfactory system, and it would be unfortunate to give the public at large any impression to the contrary.

5. From time immemorial the medical profession has been regarded as the natural sponsor not only of individual but also of community health. Legal provisions relating to standards of medical education and

privilege of the practice of medicine rest on this foundation. Whether this service in future shall be rendered by the profession in cooperation with health authorities or be made incumbent on the legal health representatives must depend on the character of the service rendered by the profession. It should be the object of the organized profession to impress on each individual physician his responsibility in this matter.

THE PHYSICIAN AND THE PUBLIC HEALTH *

HARLOW BROOKS, M.D.
NEW YORK

I speak today from the point of view of a medical man engaged in active practice in one of the great urban centers. I shall consider particularly those various points on which the medical practitioner in these centers is likely to be, or may be, out of complete sympathy with the activities of lay organizations that have largely interested themselves in questions pertaining to public health matters.

At the outset I wish to state that I, and I believe all my fellow practitioners, honor, respect and crave the assistance of every lay person and organization that is devoted to altruistic service to the public, to the alleviation of suffering, and to the betterment of mankind. Whatever I may say in the way of criticism is meant to be in the nature of a constructive one. Our purpose is, and should be, identical. As to the methods by which this may be best accomplished, I believe that there is often room for argument and full consideration.

If we may grant, at least for the sake of argument, that my point of view is to be that of the professional in regard to matters of health as contrasted to that of the amateur in health matters, I do not think that I am asking too much. I will consider also as professional health workers equal with ourselves all those who in their training in hygiene, bacteriology, pathology, anatomy, physiology and therapeutics have equaled the requirements in these subjects of a Class A medical college. In this assumption I feel that whether or not such persons have a medical degree and a license to practice, they are equipped to be grouped with us as professionals and not as mere amateurs.

Sanitation, epidemiology and the executive features of public health work must be considered only as specialties in medicine, just as we practitioners group ourselves as neurologists, surgeons, internists, and so on. Without a basic training in the elemental medical sciences there cannot be true specialization in such work any more than the surgeon can be permitted to practice his craft without a careful training in physiology, in bacteriology and in the other essential fundamentals.

I wish also to advance as my ideal of the specialist in public health that splendid group of officers comprising the U. S. Public Health Service, and those in the medical departments of the army and navy, whose everyday function it is to apply the problems of public health in a practical way. To such men the medical profession as a whole gives its sincere confidence and full cooperation. I do not know of any exceptions. We have every confidence in all those specialists in public health who are legitimately specialists. We have a quite natural suspicion of those lawyers, politicians, business men, preachers, and otherwise unoccupied ladies, grouped so loosely and so thoughtlessly as "social workers," who do not have basic training or understanding of those subjects to which we have so seriously and with single hearted zeal devoted our whole preparation and life.

I was astonished the other day to read the statement of a worker in public health that the practicing medical profession was often found in conflict with public health activities. I cannot understand such a position unless the public health service in that instance was interested, as are some of the lay organizations, in activities basically contrary to the teachings of medical science and to the welfare of the public and its infirmities, just as some lay organizations advocate antivivisection, antivaccination, and various quack institutions and projects.

The statement has also been made that because the medical man is chiefly concerned with the sick person he cannot, therefore, be interested in the problems of the community, which, if I understand it properly, is made up merely of collections of individuals. The absurd accusation has also been laid against the medical practitioner that he is not interested in the prevention of sickness but only in its alleviation. I am sure that the individual who made such a silly and entirely unfounded statement never had a family doctor. The family doctor is and always has been the very bone and sinew of all successful methods for the prevention of disease. Little has ever been produced in the prevention of disease which has not been based on the preliminary work of a physician, or on that of the trained scientist who has the identical preliminary schooling which the physician must secure before he is permitted to graduate or to take out his license to practice. The doctor has never opposed true medical progress, but bitter experience has taught him to view with great caution the emanations of untrained, unthinking, irresponsible and often unscrupulous dabblers in health and medical practice. The practitioner is slow to accept unreasonable theories, to jump at cure-alls or to contract the hysteria which in every epidemic is likely to develop in the largely unoccupied masses.

The accusation has also been made that the medical practitioner is not public spirited, not a nationalist—this, mind you, of a profession that recently voluntarily gave 20 per cent of its personnel, old and young, in a great national calamity; of a profession the members of which are acting generously, anxiously and efficiently on the boards of every educational advance, every church and charitable venture; a profession that has always identified itself personally and as a united front in every good project of humanity. I know that there are those who feel that hospitals would be beautifully efficient institutions if only there were no doctors to demand that business step aside for the welfare of the sick, and that organized charity reach the unfortunate instead of spending its efforts and funds on a perfect business institution. That the doctor is not a business man, I confess. The recent revelations of the income tax proves that definitely.

We are that single profession which statistics show devotes voluntarily from 25 to 45 per cent of its time to unremunerated personal charities, mostly to that large and generally inarticulate mass of the unfortunate

---

* Read before the Conference on Public Health, Chicago, March 24, 1927.

which are the secret wards of every honest medical man. Do any of you know a single practitioner who does not devote to the very best of his ability a large percentage of his time, without remuneration, to the care of the unfortunate sick?

But enough of this foolishness. Criticisms of this ganglion cell-less type simply indicate the motivation of its authors. As General Harbord, a great soldier and a greater citizen, has recently said, most of this propaganda originates from the activity of a pathogenic bacillus known as the paid executive secretary. He has never flourished in the culture medium supplied by the medical profession.

Misunderstandings have arisen, it is true, honest misunderstandings between the profession and some worthy public health activities. Was there ever progress without argument and criticism? There is little or none in those activities controlled by the United States Public Health Service or in those of the state or city health departments when they have been controlled and directed by trained medical men. The commissioner of health of our great, generous and progressive city has in a recent bulletin thanked the state and county medical societies and the Academy of Medicine of New York, all of which he terms his allies, for the full cooperation and assistance we have given him. I have never known it to be otherwise when we have had, as we now have, as our commissioner a physician who still remembers his training and his origin, and who still believes in medical ethics, which, I take it, is only a concrete application in our profession of the Golden Rule.

Misunderstandings between the profession and social activities along the line of public health have almost without exception originated when we have been asked to abrogate, to forget, our scientific training, or when our code of ethics has been ruthlessly ignored. Are we ready to scrap our code of ethics? If so I wish to leave medicine and become an arctic explorer or a field archeologist and be no longer a doctor. There is no more reason why medical ethics may not be applied in public health than in any other specialty in our profession. No efforts at progress will succeed until lay organizations are brought to realize that we shall first uphold the principles that have made modern medicine and the true physician of all times.

I believe that I may rightfully claim an intimate acquaintance with the members of my profession in the large community in which I live. I know few rascals in the profession; I know very few men who do not value their professional standard as high as life itself. I do not know of any practitioners who do not gladly give up a very considerable portion of their time to unremunerative and largely secret charities. I know but a few men who do not read the current journals and who do not buy, even at the prevailing high prices, standard text and other professional books. I know very few doctors who do not try to keep abreast of the times. I know few doctors who die rich; I know many who might do so if they were willing to conduct their profession as a business. I am sorry to say that I also know a few doctors of very exceptional ability who never attend medical meetings and who give none of their time to the necessary routine of society work. They are unknown outside their personal practice and perhaps to a few specialists and consultants, yet they are also an honor to their calling. I know many doctors who devote their time as employees of business institutions. Some of them are men of considerable capabilities, but they have been dwarfed and curtailed by business control. Few of them frequent the libraries or medical societies. Eventually they become worth no more than the salary they receive. They are the result of the vaunted "business control of medicine." Many of them devote their time as secretaries and agents for organized charities. They are despised by their employers, who would never trust to them their lives; they are useless to the profession, and they eventually become so "organized" that they might as well be classed merely as lay secretaries.

What does the physician in family practice resent in the activities of public health? He resents nurses doing the work of physicians, making diagnoses and dictating treatment which the family physician shall carry out. Do you blame him? He resents the underpaid, time-serving employee of the department who from the wealth of his inexperience minimizes to school children the work and ridicules the respect of their family doctor. He resents, too, wholesale septic vaccinations and other evidences of legal but bad practice. He resents the snap diagnosis of an employee of the department on a case to which he has perhaps given serious and experienced study. He resents being directed the institution of treatments which he knows from his journals and from his societies to be still in the experimental stage. He has often just cause for his complaints, for he knows himself to be the better man.

This is all easily correctable. Nurses are nurses until they have studied medicine and legally qualified themselves as practitioners of medicine. They should not be allowed to do as an agent of public medicine work which the law does not permit them to do as private individuals.

Physicians working under the direction of public health institutions must be sufficiently remunerated so that competent men may be retained. Such men will always meet courtesy, compliance and cooperation; the cheap man will not.

In a recent publication, attention has been drawn to the great economic waste which results in the duplication of work prosecuted by the many lay directed organizations. This could be avoided were these activities directed by professional, and not jealous lay, skill. Concentration under professional control would result in such economy that the money of the public would not be so wasted, and at the same time adequate salaries could be paid so that professional workers in this special field of medicine might properly compare their lot with that of the successful teacher or practitioner of medicine.

Employment of young physicians at meager salaries robs the profession of the material from which it should recruit its general practitioners, now the greatest need of the profession. I often tell my interns as they graduate that the worst thing that could happen to them would be to receive a salary on which they could live from some lay institution in which the professional experience does not reward the service; for many of them later in life would not dare to give up their salaries and start out for themselves. Some of the brightest youngsters I have ever known have been ruined by such activities. They typify the business and nonprofessional controlled society.

Another matter in the control of professional institutions by the layman lies in the demands made on the young men for service inadequately repaid either by the experience gained or by the pay received. Many of our private lay controlled hospitals are sinners in this matter. Some of them are notorious for their ruthless but entirely businesslike exploitation of the young physician.

Wealth, under the guise of charity and public health progress, more than seldom dominates even medical education. High endowments without professional control have dwarfed medical teaching in more than one institution. This is a matter for your attention.

Public medicine cannot be divorced from private medicine, except at a loss by both. The most potent and influential teacher of public medicine and of practice is the physician in contact with his patient. No public medicine can succeed professionally that has not the endorsement of the average physician.

The value and the influence of the average practitioner is beyond the comprehension of the executive who is himself not conversant with the details of medical practice or who has through lack of experience so estranged himself from his profession and its practitioners that he fails to comprehend even its purposes. He is likely to develop from his ignorance of real medicine and its problems a superiority complex of particularly inexcusable type. This is the disease from which many public health workers suffer; they are the ones who criticize the average physician. The public health worker must keep in touch with the general science of medicine and not criticize his brother who perhaps in the stress of his work has neglected to remain fully conversant with the special methods of public health. There are few surgeons who appreciate the labor of the psychiatrist; each considers the other something of a medical invert.

We of the medical profession believe that a license to practice should be granted only after four or more years of study in an accredited school, superimposed on a preliminary education of no mean extent or small cost. That this idea is not held by the public at large is only too vividly shown in each state each year by all manner of cults, often backed by the clergy, well intentioned philanthropists, financiers and people of all sorts, intelligent and otherwise.

If we are correct and well founded as to our requirements as regards the private practitioner, why is it that the practitioner of public health may be self anointed, as it were? Is the public to be less protected than the individual? May we not apply here also the invidious comparison dictated by the Egyptians of old, who admitted that Saul had slain his thousands, but David his tens of thousands? And there are many Davids engaged in their favorite avocation of public health, how many only the properly prepared medical practitioner is able to judge.

Surely there are few of you who have not read in a recent number of the *Atlantic Monthly* the exceedingly covert but telling and just arraignment of the control of medical education by self perpetuating bodies such as the General Education Board and other similar endowments. Is it not apparent to most of you that we are allowing precisely the same condition of affairs to dominate the field of public medicine? An exceedingly thoughtful and just editorial[1] appeared in The Journal, March 5, on this very subject.

I have also noted in The Journal an editorial entitled "The Physician's Responsibility in Preventive Medicine."[2] There are few, if any, practitioners among my colleagues in New York who are not willing, more than willing, to accept these implied responsibilities, few who do not subscribe whole heartedly to every word expressed in this timely editorial.

I recall a time not so long ago when the medical profession of my city did all in its power to increase the authority and powers of the United States Public Health Service, even to the extent of turning over to them the sanitary control of our port. Those of you who know the enormity of this agency in our city life can appreciate what this meant. The project was defeated. Can any of you surmise why, when the great body of our practitioners wished it? Again the subtle workings of Bacillus harbordensei.

I should like to ask General Cumming whether his wonderful organization has felt a lack of cooperation on the part of the practitioners of my city toward the activities of his workers. I do not believe it possible, and as I said at the outset of my paper, I think that I know my practicing colleagues of New York.

It seems to me that it is a very simple matter to readjust our differences and to bring to us the whole hearted support of the public. We need them, they need us. We particularly need their money, for we are a poor people financially—we give already, perhaps, too much of ourselves and of our funds to the unfortunate. Let us do all in our power to unite the public to us, let us acquaint them with our purposes, with our needs, let us invite them into our confidence. Let us frankly give our ideas to the public press, let us warrant in every way the full confidence of those whom we serve. Please remember, however, that every one of our public has his doctor, and that he has not and cannot have a higher opinion of the profession than he has of his own doctor. We and our reputation in every respect are absolutely in the hands of the practicing physician. May it never be otherwise!

With all this, with the breaking down of our no longer necessary brahministic seclusion, let us not for one moment give up our professional ideals, our traditions and our ethics. If we do we become no more than business men. In the eyes of the public we still constitute a priesthood. This reputation has been built up on the example of the family practitioner. If we lose this we lose all, and most of all the confidence of the public whom we still seek to serve, yes, even more than the God of science.

I take it that this meeting is called for something constructive. To an astonishing degree the American Medical Association possesses the confidence of the physicians of this land. It is our professional republic, a rule of ourselves by ourselves. What can the American Medical Association do to solve this problem?

It seems to me that the answer is a simple one, though the trail is rough and the desired objective far ahead. There are many wire entanglements, difficult trenches to take, machine gun nests to dislodge, and in many instances a well organized resistance against the "Medical Trust"—that is, against us, serious minded, progressive and ethical men who make up this organization. There are many Elijahs, mostly of the Bryanesque type, commanding against us. Old "General Reformer" has already laid down his barrage against us; heaven knows what he is going to do without the doctor when he has so hemmed us in by restrictions and decimated us by levies that we have as a profession become entirely secularized. But that does not concern him. It does concern us and our future usefulness.

---

[1] "The Perils of Magnanimity," editorial, J. A. M. A. 88: 726 (March 5) 1927.

[2] The Physician's Responsibility in Preventive Medicine, editorial, J. A. M. A. 88: 484 (Feb. 12) 1927.

Let us win the enemy over to us by concerted action by the same devoted and disinterested zeal which has always typified the profession, and to which alone is progress in medical science due.

Let this great body insist on the control of its own members. Let it demand that it, and not the zealous amateur, shall control our education, our position in this nation, and even our discussion of medical matters.

Let us through our state and county societies, under the direction of the great parent body, enlist every member in the work of public health. Let us invite the cooperation of every honest lay body; but we must dominate and insist that the professional standards which have made medicine shall still prevail, and that medical science shall still control medicine, in all its applications.

Through our medical organizations let us detail lecturers for public occasions. Through our own authorized members let us give out to the public press of the land authoritative statements of such an enlightening character that the public will listen and take heed.

Let us take over the city, the county and the state public health organizations; too many of them are now taking us over. Let us teach our students and young practitioners the essentials of public health as we now teach them an outline of medicine, of therapeutics and of surgery. Let us in general so prepare ourselves that we are qualified to act as public health officers. Then, and then only, shall we be able to take over and to control public health in its every aspect. But we must demand at all times that the traditions and ethics of medicine shall be respected, that only the competent shall rule.

I believe that the intelligent public is really with us. I believe that they are more than willing to meet us half way, and to devote under scientific professional control the enormous sums which are now dissipated at a tremendous economic waste, mostly under the debauched name of "charity." Encourage in public health such leaders and creators as we have developed in bacteriology, in chemistry, in physics, in surgery, in physiology and in all other essential components of medicine. Insist that they shall also enjoy a commensurate reward financially, and the dignity of a professional, and not of a social or political, position. This cannot be achieved except through professional control.

Finally, may I say for the practitioners of New York that we are back of every sensible measure of accredited preventive medicine. We are more than willing to play our essential part in the program of public medicine. We are not, however, a class prone to accept without due consideration the vaporings of every volunteer amateur Moses. We are prepared and waiting for the leadership of qualified, scientific medicine in this great undertaking. We shall as a body welcome the control of this great project by accredited representatives of American medicine, whether it be by the American Medical Association or by any other similar body of equal ability and proved authority, if such other there be.

Recent studies [1] on the geographic distribution of rheumatic fever in the United States have shown that the incidence of the disease is greater in the northern than in the southern regions of the country. Owing to the fact that rheumatic fever is not a reportable disease, it is necessary to utilize hospital records or mortality statistics to obtain information regarding its frequency. Therefore Harrison and Levine studied hospital admission rates for rheumatic fever in a number of cities in the Northern and Southern states and found that "rheumatic fever and rheumatic heart disease are much more common in Boston than in Richmond, Oklahoma City, New Orleans and Galveston. Baltimore and St. Louis occupy intermediate points." Faulkner and White, in their studies, have investigated hospital reports from different parts of the world. They state that their observations "are valuable chiefly in showing what wide differences do exist in different parts, and in suggesting that colder and wetter countries or districts tend to have a higher incidence."

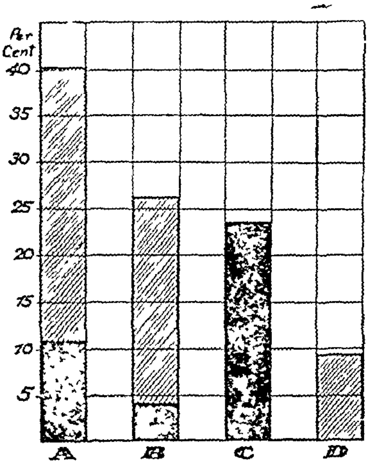

Chart 1.—Replies received from ninety-four hospitals to which rheumatic fever questionnaire was sent. *A*, percentage of hospitals supplying utilizable data; *B*, percentage of hospitals supplying incomplete or unsatisfactory data; *C*, percentage of hospitals reporting "information not available"; *D*, percentage of hospitals not replying. The percentage of each group of hospitals returning the dollar bill is indicated in black.

These authors did not attempt to describe the yearly variations in the incidence of the disease, for they give only one figure for each hospital, which represents the average yearly incidence of rheumatic fever for the number of years investigated. Since Hirsch,[2] Newsholme [3] and Pribram [4] have pointed out the cyclic character in the incidence of the disease, this method of averaging the annual frequency figures does not give any conception of the variation in the rate of the disease over a series of years.

Extensive studies of the geographic distribution of rheumatic fever have been carried on in the British Isles, where the disease is believed to be especially common. On the one hand there is the school[5] which adheres to the belief that the high rates in the incidence of this disease are associated with low annual rainfall, and indirectly with the diminished ground water. In contradistinction to this point of view, other workers[6] have presented evidence which suggests that the highest incidence of the disease is in the damp, rainy and cold regions in the geographic areas they investigated.

Our study has concerned itself with an attempt to determine the annual incidence of rheumatic fever over a significant period of years in a representative group of hospitals in the United States, its possessions, and Canada. It is by necessity an unfinished piece of work because of the difficulties encountered in gathering a representative portion of the vast material required for the development of reliable conclusions. However, the data are presented in the hope that they may act as a nucleus to which more material will be added.

METHOD

A group of ninety-four general hospitals distributed throughout the United States, its possessions, and Canada were selected from the American Medical Directory as the source of the data. In choosing the series, hospitals of long standing, with more than 200 beds and with teaching affiliations, were given the pref-

* The yearly number of cases of rheumatic fever (RF); the yearly total hospital ward admissions (includes medical and surgical admissions) (TA), and the yearly medical ward admissions (MA) in forty hospitals in the United States, its possessions and *Canada*.

The collection of data was carried out in the following manner: A letter stating the purposes of the epidemiologic survey was sent to the superintendents of the hospitals selected for study or, in some cases, to the chief medical officer or professor of medicine. This letter contained a form of five columns to be filled in by a clerk in the record room. The captions of the columns were: Year (1875 to 1925); Number of Cases of Rheumatic Fever; Number of Cases of Chorea; Total Number of Admissions to the Medical Wards; Total Number of Admissions to All the Hospital Wards. Directions were given that only clinically diagnosed cases of rheumatic fever and Sydenham's chorea admitted to the house were to be included in the report. A dollar bill was enclosed with the form for the remuneration of the clerk who might perform the task. From our own experience we had found that the work could be completed in approximately one hour.

By accepting statistics for cases admitted only to the house, the possibility of determining the number of individuals with these diseases who were being treated in the outpatient departments was precluded. Although such information might have been extremely valuable, the index systems and character of diagnosis in the majority of outpatient departments made it advisable to exclude such material from our study.

The response to this letter and a series of follow-up communications is graphically shown in chart 1. Of ninety-four requests for information, thirty-eight, or 40.5 per cent, responded with data which were utilized in the survey. Of this group, 29 per cent returned the dollar bill. A second group of twenty-five, or 26.5 per cent of the total, returned forms which were incomplete or unsatisfactory. Of this number 16 per cent returned the money. A third group of twenty-two, or 23.5 per cent, returned the dollar bill with the statement that their record system made it impossible or too difficult to gather the desired information. The fourth group, numbering nine, or 9.5 per cent of the total, failed to reply to our letter and follow-up communications.

The data from the second group of twenty-five hospitals were considered incomplete or unsatisfactory on the basis of one or more of the following criteria:

1. Less than 1,000 medical admissions, or 3,000 total admissions per annum.
2. Data covering a period of less than a year.
3. The obvious inaccuracy of the figures.
4. An expression of uncertainty from the sender of the report as to the validity of the information.

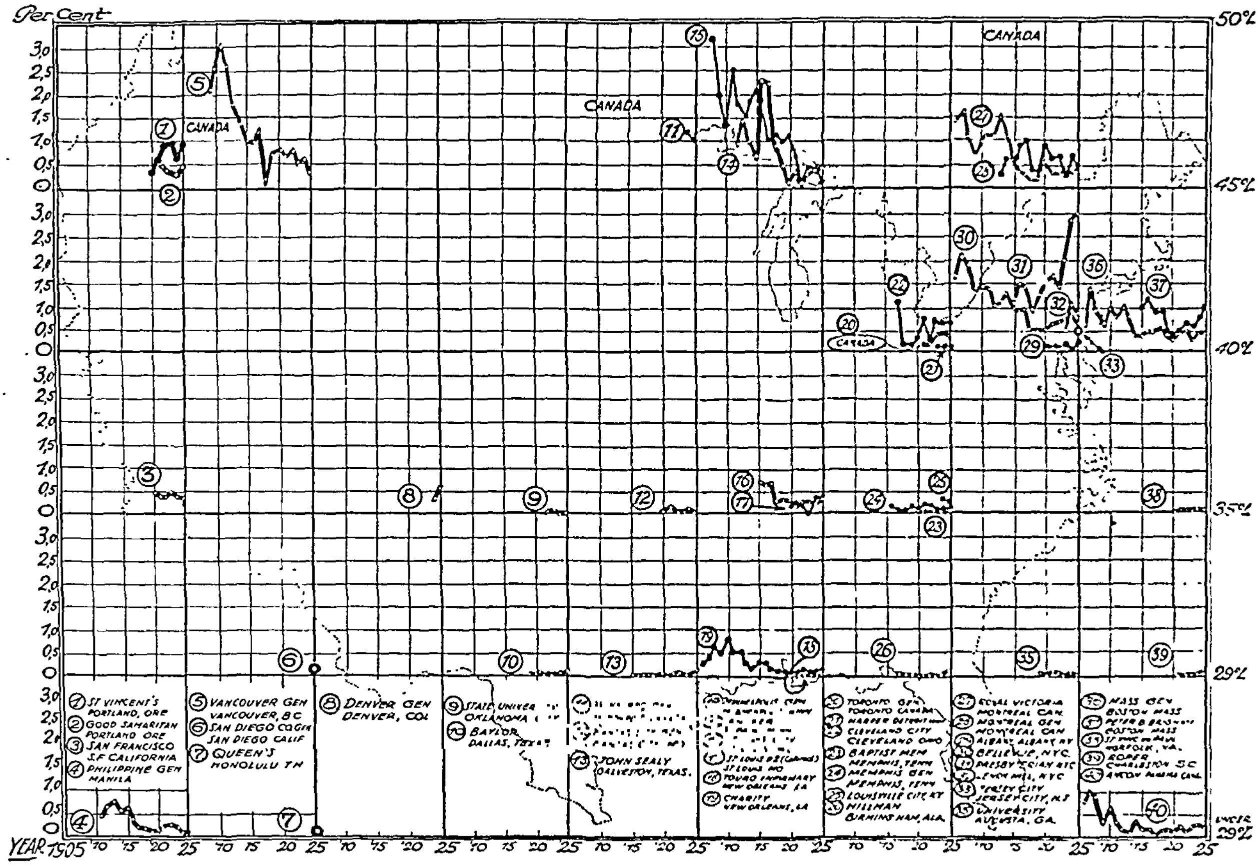

Chart 2.—Percentage of annual total admissions (includes medical and surgical) diagnosed as rheumatic fever in forty hospitals in the United States, its possessions, and Canada. Each curve in the larger squares represents an individual hospital which is situated in its approximate geographic location. The name of each hospital appears in the lowest set of squares. Note the highest percentages of rheumatic fever in the northern latitude areas as contrasted with those in the South.

Those reports which showed striking variations in the rate of incidence of rheumatic fever in several hospitals in the same city were investigated with regard to the accuracy of their figures. A series of follow-up letters was sent in an effort to obtain satisfactory correction of the questionable data. When it was found impossible to make the returns compatible, the figures for the entire city were discarded. There were six hospitals in this group, three in Philadelphia and three in Chicago. In the latter city, the markedly divergent results were found to be due to different methods of classification of the disease. For instance, one hospital included all its cases of rheumatic fever under the heading "Acute Arthritis." It was impossible to determine how many of the cases included in this category were actually gonococcal, streptococcal or other forms of arthritis. On the other hand, another Chicago hospital classified only a portion of its rheumatic fever cases as such, the remainder being grouped under the headings: "Acute Articular Rheumatism," "Acute Rheumatism," "Acute Arthritis" and "Acute Polyarthritis." Since the error could not be rectified, all the material was excluded from this report. A similar difficulty was found to exist in three Philadelphia hospitals. Here the divergence of rates for the disease in the various institutions seems to rest, in part at least, on selection of cases. In this instance, it was again felt advisable to discard the data for the entire city.

Two hospitals reported rates of rheumatic fever lower than that for chorea. Since this fact is contrary to what is known of the relative hospital frequency of the two conditions, and since other hospitals reported many more cases of rheumatic fever than chorea, we considered the data from these two hospitals of questionable accuracy and therefore discarded the material.

The variable returns for the incidence of chorea made it seem highly probable that these figures depended on the size of the children's wards in connection with the hospital. These figures are therefore not included in our study. They were useful, however, in judging the accuracy of the figures submitted for rheumatic fever incidence, as before described.

PRESENTATION OF DATA

The presentation of the material from the thirty-eight hospitals submitting acceptable data and the two Boston hospitals which were personally canvassed, a total of forty hospitals, is accomplished by means of the accompanying table and charts 2 and 3. The table presents the figures for rheumatic fever admissions, total admissions to all the hospital wards, and total admissions to only the medical wards for the years 1906 through 1925 for each hospital.

Charts 2 and 3 are similar to each other in their construction. They contain graphs for each of the hospitals of our series. These individual graphs are plotted in their appropriate place in one of the forty-five larger squares which have been superimposed on a map of the United States. The graph for each hospital lies approximately in its correct geographic location. The abscissas, or base lines, correspond to the latitudes 45°, 40°, 35°, 29°, and "under 29°." Every hospital whose graph has 40° as a base line is situated either at 40° latitude or between 40° and 45°, and so for the other latitudes. The abscissas are divided into years extending from 1905 through 1925. The ordinates are divided into intervals representing the percentage of rheumatic fever admissions in terms of either the annual total admissions (chart 2) or the annual medical admissions (chart 3).

Those squares in the charts which lie on the Eastern Seaboard often contain more than one graph, while many in the Middle West contain no graph. The latter condition is due to the fact that we were unable to procure reliable data from these thinly settled areas. There are five Canadian hospitals which are accordingly designated. In the lowest squares are graphs from a Philippine, a Hawaiian and a Panama Canal Zone hospital. The number opposite each curve will be found again in the lowest squares, accompanied by the name and location of the hospital supplying the material from which the curve was constructed.

The original data are to be found in the table. The hospital reports are so arranged in the table that they correspond in position with the graphs on the charts, reading from left to right.

Chart 2 is entitled "percentage of total admissions (includes medical and surgical) diagnosed as rheumatic fever." To obtain the percentages which are here graphically represented, the number of cases of rheumatic fever admitted yearly to each hospital was divided by the total number of patients admitted to all the hospital wards during the same year. Chart 3, entitled "percentage of annual medical admissions diagnosed as rheumatic fever," is prepared in the same manner from the annual number of cases of rheumatic fever and the medical admissions.

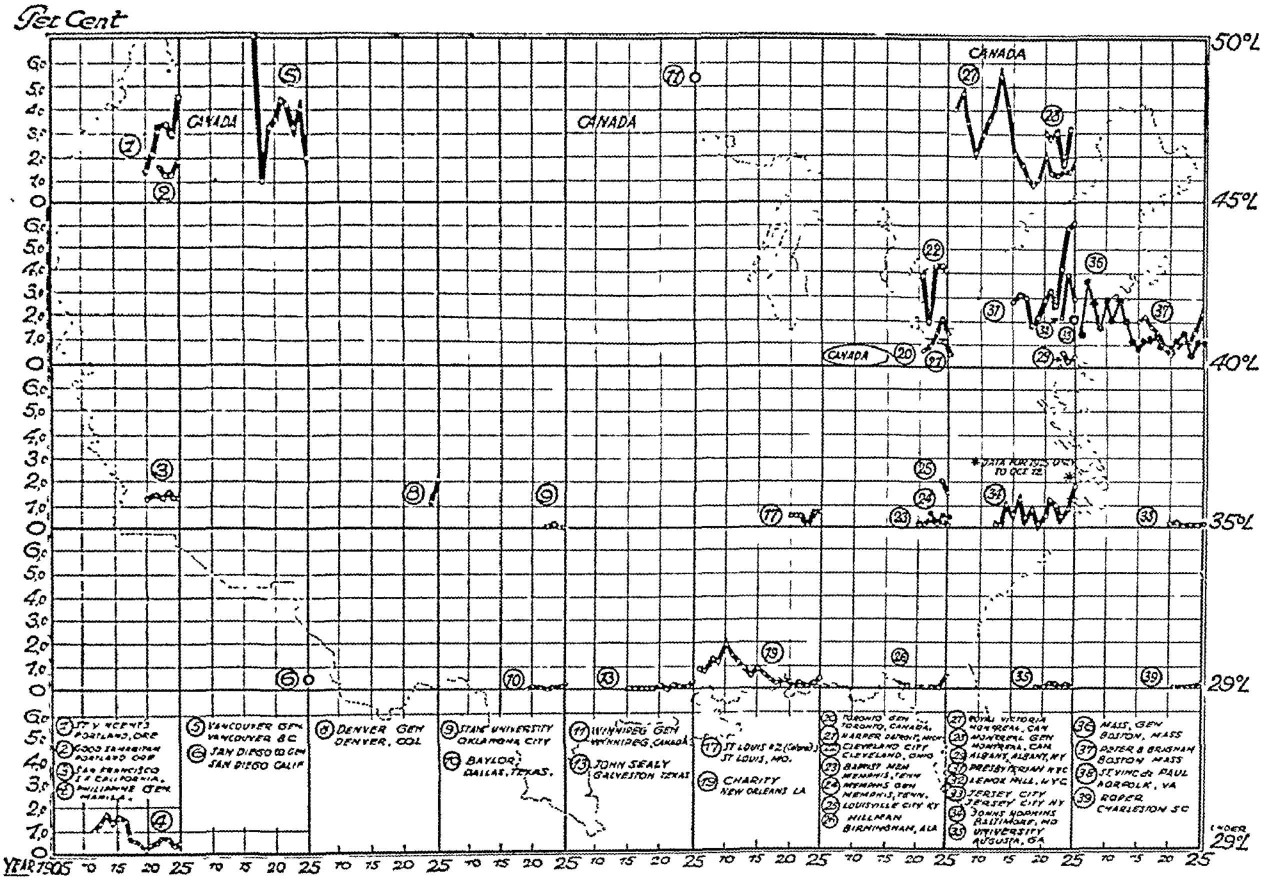

Chart 3.—Percentage of annual medical admissions diagnosed as rheumatic fever in thirty-two hospitals in the United States, its possessions and Canada. Each curve in the larger squares represents an individual hospital which is situated in its approximate geographic location. The name of each hospital appears in the lowest set of squares. Note that the percentage of rheumatic fever is greater in the northern latitude areas than in the southern.

Eight of the hospitals were unable to supply figures for the medical ward admissions, although they did submit figures for the total ward admissions. It is for this reason that it was necessary to present the rheumatic fever figures in terms of both medical and total ward admissions. The incidence of a medical disease when estimated in terms of the total admissions to all the hospital wards is likely to be badly distorted, as one hospital may have large obstetric, neuropsychiatric, tuberculous and contagious services while another has only medical and surgical wards. This, of course, means that a comparison of the incidence of rheumatic fever in terms of total hospital admissions in two such hospitals would give a false view of its relative prevalence in the two institutions. However, the curves from those hospitals which are represented in both charts 2 and 3 are of the same form and usually of the same relative magnitude. Therefore, the percentage of rheumatic fever in terms of total ward admissions for the eight hospitals represented only in chart 2 is probably sufficiently accurate to give an indication of the prevalence of the disease in these hospitals.

COMMENT

In any biologic experiment there are many variables which make perfect uniformity in the results impossible. Such variables have been particularly numerous in this survey because of the general character of the undertaking. Differences in the classification of the disease, the selection of cases in teaching hospitals, the susceptibility of the various racial groups represented in different portions of the country, the accuracy of diagnosis, and the readiness with which people in different regions of the country avail themselves of hospital privileges are all factors that may have affected the figures. These influences can scarcely be evaluated in estimating the significance of some of this information, and therefore a considerable reserve must be manifested in drawing conclusions from these data, which are by necessity of a limited order.

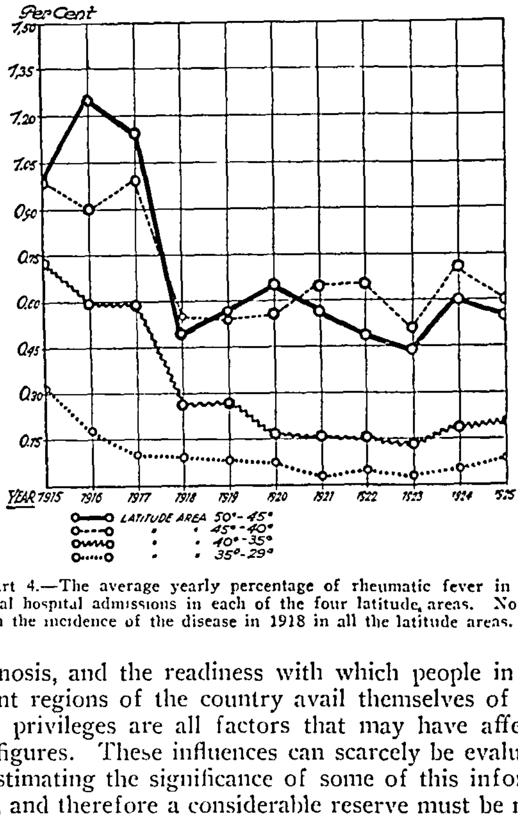

Chart 4.—The average yearly percentage of rheumatic fever in terms of total hospital admissions in each of the four latitude areas. Note, the fall in the incidence of the disease in 1918 in all the latitude areas.

Inspection of charts 2 and 3 demonstrates that rheumatic fever is present in varying percentages in all the hospitals of our series. Its frequency, however, diminishes markedly and quite consistently as one travels from north to south. In most Southern and Near Southern hospitals, whose data are shown in the lower sets of graphs, the relatively flat curves close to the base line indicate that the incidence of rheumatic fever in hospitals in cities such as Dallas, Galveston, Oklahoma City, Kansas City, Memphis, Birmingham, Augusta and Charleston is very low. An inspection of the figures of these hospitals shows that despite the flatness of the curves there is, however, a yearly fluctuation in the rate of the disease. But with such a low incidence, the number of cases of rheumatic fever in a year may double or triple that of the preceding year without making any prominent change in the graph.

The relatively high rates of rheumatic fever in the Northern hospitals stand out in contrast to this picture in the South. In order to show this variation more simply, chart 4 was constructed. To obtain the figures for this chart the yearly rheumatic fever and total admission figures for all the hospitals lying in each of the upper four latitude divisions were added together and the average yearly rheumatic fever incidence, in terms of total hospital admissions, for each of the latitude areas concerned, was thus determined. The Philippine, Hawaiian and Panama Canal Zone hospitals were omitted from this chart.

These average yearly figures for each of the latitude areas 50°-45°, 45°-40°, 40°-35° and 35°-29° are graphically represented for the years 1915 through 1925. The curve for latitude area 50°-45° is made up of an equal number of Canadian and northern United States hospitals. Running in close association with this curve is the graph for latitude area 45°-40°, which represents hospitals grouped for the most part on the Northeastern seaboard, since we were unsuccessful in obtaining reliable data from more western institutions in this latitude area. In contrast to the relatively high rate of rheumatic fever shown by the graphs for the upper two latitude areas, the hospitals lying between 40° and 35° show a much decreased incidence of the disease, and the most southern hospitals an extremely low incidence. In judging the significance of these average figures, it should be remembered that in the earlier years 1915 to 1920 there are fewer hospitals represented than in the years 1920 to 1925. It is also important to realize that all those hospitals which have supplied us with figures extending over many years lie on a body of water—the Great Lakes, the Mississippi River or one of the coasts.

All the hospitals included in this study which have given figures over a sufficiently long period of time show, on the average, a higher yearly incidence of rheumatic fever previous to 1918 than from 1918 through the later years of the study. In this connection Atwater[7] has recently shown that "there is a definite and rather consistent downward trend in the mortality from rheumatic fever in the U. S. registration area between 1900 and 1923."

In connection with the drop in the incidence of the disease which is found here in 1918, the figures for rheumatic fever among enlisted men quoted by Faulkner and White[1] are of interest. Their data extend from 1913 through 1922. The average "admission ratio per thousand white enlisted men" in the United States for "acute rheumatic fever" for the years 1913 through 1918 is 6.69, while for 1919 through 1922 it is 2.47. In the period 1913-1922, the two years of highest incidence are 1917 and 1918. For the negro enlisted men, the average admission ratio for 1913 through 1918 is 6.11, and from 1919 through 1922, 3.45.

The four curves of chart 4 representing the average incidence of rheumatic fever for the four latitude areas are, practically speaking, flat from the year 1918 through 1923. During the last two years, 1924 and 1925, there has been a tendency toward an increased rate of the disease in some hospitals. This increase is most marked in the Presbyterian Hospital in

---

[7] Atwater, R. M.: Studies in the Epidemiology of Acute Rheumatic Fever and Related Diseases in the United States, Based on Mortality Statistics, Am. J. Hyg. 7: 343-369 (May) 1927.

New York. We have been advised that this is not due to selection of cases. Other hospitals which show the same tendency are St. Vincent's, Portland, Ore.; Peter Bent Brigham, Boston, and Johns Hopkins, Baltimore. In chart 4 this rise is faintly indicated, but it will be necessary to have data for subsequent years before it can be known whether it is real or only apparent.

The rise in the incidence of the disease during the years 1924 and 1925 is more distinctly indicated in chart 5. Chart 5 is prepared in the same manner as chart 4, but presents the average percentage of rheumatic fever for the four upper latitude areas in terms of medical admissions. Because so few hospitals gave figures for their medical ward admissions over a longer period of time than six years, this chart covers only the years 1920 through 1925.

Swift,[8] in commenting on Lambert's[9] report that rheumatic fever was decreasing in frequency among patients admitted to Bellevue Hospital between the years 1906 and 1919, says:

> If the rheumatic fever is a specific infection, we would expect it, like other acute infectious diseases, to run in certain periodicity in incidence. . . . The influenza epidemic on the incidence of other acute diseases must be considered. Vital statistics have shown that there has been a marked falling off of tuberculosis, chronic cardiac disease, and other diseases, following the influenza epidemic. It is possible that patients who are subject to infection may have succumbed to influenza, and for that reason there are fewer such patients to contract rheumatic fever.

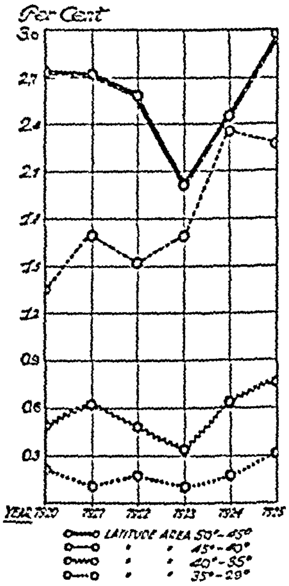

Chart 5.—The average yearly percentage of rheumatic fever in terms of medical hospital admissions in each of the four latitude areas. Note the rise in the incidence of the disease in the years 1924 and 1925.

Of the cyclic character of the disease, as described especially by Pribram[1] and Newsholme,[3] there is very little that can be said from the figures presented here. There are yearly fluctuations in the percentage of rheumatic fever patients received in each hospital. For instance, a particularly prominent jump in the incidence of the disease is reported for the years 1916 and 1917 at the Minneapolis General Hospital. Yearly fluctuations are much more marked in all the curves previous to the year 1915 than subsequently. If all the hospitals showed similar fluctuations in the same year, it might justifiably be called an epidemic. But since no two hospitals, even in the same city, consistently have their peaks of the disease at the same time, we do not attempt to explain the yearly fluctuations.

This material is presented not because it is considered complete or accurate but with the hope that we may receive correction of errors in the material presented, information from hospitals which have already submitted data that we have been unable to utilize because of variations of classification, and replies from hospitals with which we have not communicated.

SUMMARY

1. The yearly admission rate for rheumatic fever in a selected series of hospitals in the United States and Canada is greater in the northern than in the southern regions of the continent.
2. In twelve out of fifteen hospitals supplying data for an adequate period of time, the average annual frequency of rheumatic fever previous to 1918 is greater than that subsequent to 1918.
3. Since the year 1918 the disease has not shown a uniform tendency to decrease in frequency in the hospitals of this series.
4. Our figures for the final two years of the study, 1924 and 1925, demonstrate an increased rate of rheumatic fever in some of the hospitals of the series. This change is most marked in the Presbyterian Hospital in New York. Other hospitals which show the same tendency are St. Vincent's, Portland, Ore.; Peter Bent Brigham, Boston, and Johns Hopkins, Baltimore.

AN EXPERIMENT IN THE APPLICATION OF DIABETIC DIETETICS

WITH REPORT ON ONE HUNDRED CASES

M. F. DeLORME, M.D.
Clinical Professor of Medicine, Long Island College Hospital
BROOKLYN

Realizing the futility of the majority of efforts made to obtain the consent of the patient with mild diabetes to hospitalization that the necessary data essential for accurate dieting and treatment with insulin may be secured, and that the excuse most frequently offered was the loss of time from work and the incidental cost, the plan outlined herein was devised and has had a year of trial with results that seem to justify its continuance. A local organization consented to finance the experiment for a year, but the plan has financed itself and the demand for the service suggests the probability that it will continue.

In the center of the retail business section of the city was opened what is called a "Diabetic Dining Room." It is conducted by a clinician with the assistance of a competent dietitian who has had special training in diabetic dietetics. Records of more than a hundred cases are available for anlaysis. Patients are not accepted unless referred by a registered physician, and no treatment of any kind is suggested except in the report to the physician. If requested by the physician, the patron will be instructed in the administration of insulin.

It is thought that this is the first successful attempt to establish a center where the physician may obtain the desired information without greatly interfering with the patient's occupation. (Patients frequently state that they would have postponed the procedure if going to the hospital had been the alternative.) Furthermore, it is believed that such data are more informative of the patient's actual carbohydrate burning capacity than that secured from the artificial existence in the average hospital.

THE PLAN

Special effort is made to provide an attractive service. In addition to the standard foods, such delicacies as the market affords are served. This impresses the patients with the fact that they are not doomed to a routine. On admission, the normal basal metabolic rate

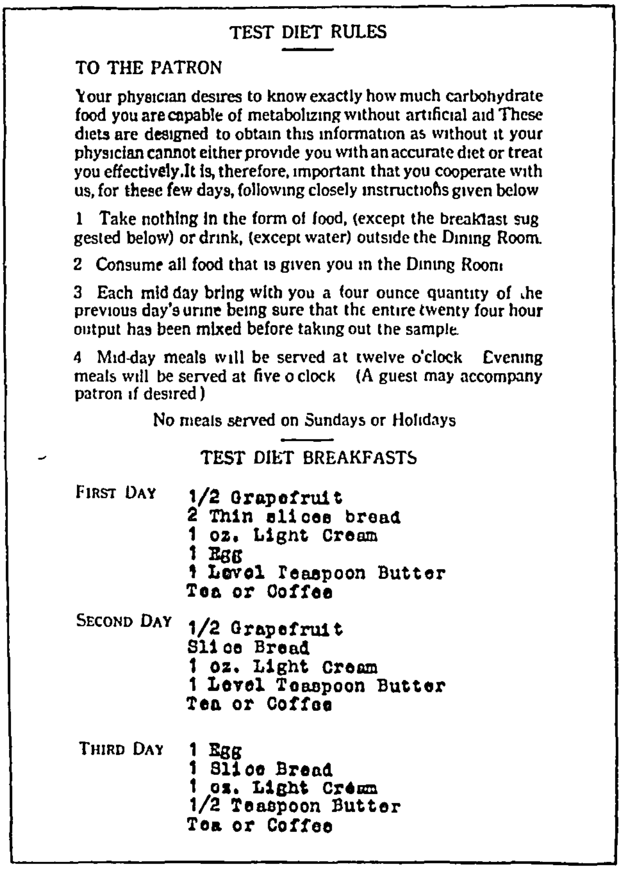
[9] Lambert, Alexander: The Incidence of Rheumatic Fever at Bellevue Hospital, J. A. M. A. 74: 993 (April 10) 1920.

(Boothby and Sandiford) is determined, and instruction in food value calculation and in the "home testing" of urine is begun. A table of calorific values of the ordinary foods is supplied and the patient is required to memorize most of it—not a difficult task. A card prescribing carefully stipulated breakfasts to be taken at home is provided (fig. 1), and the patient is told to follow carefully the stipulations and report the next day for his midday meal, when the actual dining room routine is begun. Only midday and evening meals are given in the dining room.



TEST DIET RULES

TO THE PATRON

Your physician desires to know exactly how much carbohydrate food you are capable of metabolizing without artificial aid These diets are designed to obtain this information as without it your physician cannot either provide you with an accurate diet or treat you effectively.It is, therefore, important that you cooperate with us, for these few days, following closely instructions given below

1 Take nothing in the form of food, (except the breakfast suggested below) or drink, (except water) outside the Dining Room.

2 Consume all food that is given you in the Dining Room

3 Each mid day bring with you a four ounce quantity of the previous day's urine being sure that the entire twenty four hour output has been mixed before taking out the sample.

4 Mid-day meals will be served at twelve o'clock Evening meals will be served at five o clock (A guest may accompany patron if desired)

No meals served on Sundays or Holidays

TEST DIET BREAKFASTS

FIRST DAY	1/2 Grapefruit 2 Thin slices bread 1 oz. Light Cream 1 Egg 1 Level Teaspoon Butter Tea or Coffee
SECOND DAY	1/2 Grapefruit Slice Bread 1 oz. Light Cream 1 Level Teaspoon Butter Tea or Coffee
THIRD DAY	1 Egg 1 Slice Bread 1 oz. Light Cream 1/2 Teaspoon Butter Tea or Coffee

Fig 1.—Stipulated breakfasts and rules

On the first day there is given a meal of low-value foods consisting of carbohydrate 100, protein 50 and fat 100, totaling 1,500 calories about equally divided into the three meals. The patient, previously instructed, collects the entire twenty-four hour output of urine and brings a sample when coming for the next day's midday meal. It was suspected at the start that this detail would be difficult of enforcement; but such has not been the experience, so much have the patients been interested in their own welfare. The urine is examined before the patient begins the second day ration; if sugar is found, the carbohydrate ration is reduced to 80 Gm.; if under this reduced ration sugar continues to appear, the third day's carbohydrate ration is made to conform to the patient's minimum carbohydrate need (1 Gm. to 1 Kg.); if sugar continues to appear on this minimum allowance, insulin is given in gradually increasing doses until the urine is sugar free. (The beginning dose of insulin was 2 units three times daily.) The urine being now sugar free, a blood sugar estimation is made to determine the renal threshold. By this time, patients are usually sufficiently familiar with food value calculations to be permitted to care for themselves at home; they are given record blanks, to be filled in at home, and are told to return in a week for a check up. In those very mild cases in which the urine did not show sugar on the first day's ration, the carbohydrate allowance was increased 10 Gm. daily until sugar did appear. In cases of severe diabetes this routine had to be modified, but in a large majority of cases it was found ample.

At each meal the patient himself is required to calculate the food value of each portion served (fig. 2). Beyond question this is the most valuable part of the procedure, for, until the diabetic patient learns to calculate accurately food values by himself, he cannot hope for any permanence in his improvement. At the beginning the patients are slightly confused, but persistence on the part of the dietitian soon qualifies even ignorant foreigners to feed themselves with surprising accuracy. Several of the patients were unable either to understand or to write English, but with the help of a school child or an English speaking neighbor, they soon became able to "live within their limits" and improved accordingly. Diabetic scales are an essential; they simplify the calculation and serve to impress the patient with the importance of accuracy in diet.

The necessary information having been secured, a copy of a carefully kept record, together with comments and recommendation (fig. 3), is sent the physician who referred the case, and the patient thereafter remains under his control.

DIGEST OF RESULTS IN FIRST HUNDRED CASES

Of ninety-seven patients who completed the course, sixty-two were women and thirty-five were men. One was a 13 year old girl. Eighty-nine of these patients continued at their usual work.

Twelve required insulin, and all were taught to administer it to themselves. Six discontinued the use of unnecessary insulin.

There were five cases of renal glycosuria. Seventy patients had + + or more of acetone on admission. Five had severe cases of diabetes and should have been in a hospital, but they refused to go, "having been there previously."

TOLERANCE (carbohydrate) C55 P. F. calories

MINIMUM NEEDS C70 P F calories

SUGGESTED DIET C85 P50 F150 calories 1890

PROBABLE BEGINNING INSULIN NEEDS 5 Units 3 times daily.

Note 1- Mrs. Black's Carbohydrate burning capacity is much below her needs. She is under weight, so we are suggesting a temporary diet (2 weeks).

2- Would suggest a blood sugar estimation every 10 days. When blood sugar is near normal Carbohydrates may be gradually increased if tolerated.

3- She is sufficiently familiar with the calculation of her own diet to permit her caring for herself at home.

Fig. 3.—Specimen of report sent to physician.

Nine days was the average time spent at the dining room, and the average cost to the patient was $22.

Contrary to expectation there was very little disposition to violate rules; instead, 90 per cent became enthusiastic in their cooperation and many of them today are remarkably proficient even in the larger aspects of the science of dietetics. The "laboratory work," as one patient termed the dining room drill in calculations, was a source of genuine interest and qualified all the patients to feed themselves at home with accuracy. All patients are told that they will be required to feed themselves at home, keeping full records (fig. 4) for a week before being discharged, and most of them proved capable of doing so when the test-period reports came back. Special stress is laid on the avoidance of gluten foods, and all are encouraged to take the same food prepared for other members of the household.

Without exception, all who completed the course have been markedly benefited; the blood sugar in all the mild cases has fallen to near normal; the obese have lost weight, and the underweight have gained. The plan is not complicated and may be employed in any hospital providing a dietitian trained in diabetic dietetics.

REPORT OF CASE

The following report is a concrete illustration of the use of this method in one case.

C. A. S., a man, aged 42, weighing 61 Kg. (normal, 70 Kg.) after a stay of three weeks in the hospital, went home with the urine sugar free and with a blood sugar of 13.5 per cent. Four weeks later he came to the dining room with a urine sugar of 3.5 per cent; he had been dieting by himself, using household measurements. He had no knowledge of his carbohydrate tolerance, nor was he able to test his urine at home. After four days of routine he was capable of accurately calculating his diet; on the seventh day he was sent home with a tolerance of carbohydrate, 70; protein, 70, and fat, 120. A week later he returned with a sugar-free urine and a blood sugar of 14.8 per cent. His "home records" were models of accuracy. Ten months later his carbohydrate tolerance had increased to 140 and the urine was still sugar free. By this time the patient had acquired such proficiency in feeding himself "by the estimation method," through a persistent use of the scales, that he took a two weeks sea voyage, leaving his scales at home (but not the Benedict's solution) and returned with a sugar free urine and a blood sugar of 15.5 per cent.

SUMMARY

1. The plan is designed to obtain essential data and to instruct the diabetic patient in the calculation of food values without hospitalization, thus permitting him to follow his usual occupation.

LINSEED OIL DERMATITIS

F. J. VOKOUN, M.D.
CLEVELAND

I began the study of linseed oil dermatitis when I was appointed industrial physician for the Sherwin Williams Company, paint manufacturers of Cleveland. In the manufacture of paint, linseed oil is an important factor. One of the plants of this company is devoted to the production of linseed oil, and it is in this plant that the cases were found.

For many years it was noticed that dermatitis was rife among the workers in the mill. The cases were usually mild—some of these persons had areas on the hands or feet which caused symptoms of itching or burning but were not severe enough to incapacitate them. However, soon after taking over the work from this plant I was confronted with three severe cases of dermatitis which necessitated keeping the men home from work. These cases were serious and brought the matter forcibly to my attention.

My recent preliminary paper[1] on this subject included a presentation of three cases, with a report of the symptoms and therapeutic procedure. Since then I have made careful investigations and gathered data which ought to be of more extended interest.

Questionnaires were sent to the larger linseed oil mills of the country, and the case reports on file with the Sherwin Williams Company have been studied for the last three years. As a result of this investigation, the following data have been collected.

W. J. Aldrich, welfare director of the Spencer Kellogg Company, which has linseed oil mills in five different cities, reports as follows:

> I have in my last twelve years' experience in connection with the linseed oil industry given this matter considerable study and have consulted various physicians on the subject, but they have never been able to give very satisfactory information. As the experience of a layman may be of interest to you nevertheless, I will answer the questions to the best of my ability in the order in which you ask them.
>
> 1. As to the number of cases reported in the last five years, I could not give you this definitely, as we have not kept a record of them. Taking all of our mills together, we think they have run into the hundreds.
>
> 2. As to the place from which the seed came that causes the oil dermatitis, our data on this point are not altogether accurate, but we think the seed from South America is more irritating than the seed from Canada or the Northwestern states. A number of years ago considerable seed was imported from India, and our experience was that this seed was more irritating than others.
>
> 3. As to the nature of the eruption, it is usually on the forearm and hands. Occasionally it has appeared on the body, about the neck, shoulders, breast and upper back, but the latter is not very frequent and only in cases in which the man has an exceptionally tender or sensitive skin.
>
> 4. As to the treatment, we have found that whenever a man has laid off for three or four days, the irritation immediately disappeared. We have also found that in most instances the irritation has been caused by the man using burlap to wipe the oil and meal from his hands and forearms between pressings, which in itself is exceedingly rough and irritating and contaminated more or less with infectious substances. We have found that the use of sterilized rags or towels in place of the burlap has caused this irritation to disappear to a large extent. In addition, a thorough cleansing with soap after the work period has been decidedly effective.
>
> We have found that it is not always an easy matter to induce the men to be particular as to the matter of this cleansing, but wherever they have followed our instructions the irritation has practically disappeared.
>
> In the more aggravated cases we have used with good results a sulphur salve combined with 16 per cent balsam of Peru. This treatment, combined with the above mentioned sanitary precautions, has cured nearly every case without the necessity of the man taking time out from his work. However, an occasional case occurs in which a man has a tender and sensitive skin and a week's layoff has been found necessary; but this is exceptional.
>
> 5. Your question as to which seed gives the greatest trouble has been partially answered in the fourth paragraph. I will repeat that the Indian seed gave us the greatest trouble. The seed we now use is from South America and Canada, and we think that from South America is more irritating than the Canadian seed. We are not inclined to think that this is an essential factor.

Dr. Barnett Kooperman, who has taken care of the men in the Spencer Kellogg mill at West New York, N. J., for the last eight years, reports:

> I believe that "linseed oil dermatitis" is a wrong term, as the linseed oil does not cause dermatitis. The inflammation is caused by the dust from the flaxseed—both ground and the seed. I have treated approximately 400 cases of linseed dust poisoning within the last five years. It seems that blond people, German, Norwegian, Swedish and all northern European people, are more subject to the dermatitis than are the Italian, Spanish and other dark complexioned people. Colored people are attacked the same as the northern Europeans.
>
> As 95 per cent of our seed comes from Argentina, I am in no position to say which seed causes less skin irritation.
>
> The nature of the eruption is a weeping eczema. It has been my experience to use a number of remedies, but I find the following the most efficient: menthol, 2 grains (0.13 Gm.); phenol (carbolic acid), 1 grain (0.065 Gm.); sufficient 2 per cent ammoniated mercury to make 1 ounce (30 Gm.). Or balsam of Peru, 1 drachm (4 Gm.), and sufficient 1 per cent ammoniated mercury to make 1 ounce (30 Gm.).

The Mann Brothers of Buffalo reported that they have no record of any linseed oil dermatitis with the possible exception of one doubtful case. Their physician made no report, so we cannot place much value in this reply.

A careful study of the records of the Sherwin Williams Company for the last three years does not reveal any report of men treated primarily for dermatitis, with the exception of the cases I have already cited. However, in a discussion with Mr. Kramer, who was superintendent at the mill for three years, I evolved that:

> 1. Minor attacks of dermatitis were very common among the workers and many of them used sulphur ointment to relieve them.
>
> 2. Flaxseed from South America was much more irritating than that from the United States or Canada.
>
> 3. The condition was rarely so severe that the men had to stop work, although occasionally they would take a "vacation" until their skins became sound.
>
> 4. During the three years of his superintendency, he saw hundreds of cases of dermatitis.

From my experience with this condition I have made several observations. The lesions are usually on the anterior aspects of the arms, the dorsa of the hands, and the anterior aspects of the thighs (in those men whose thighs touch the oil in their work). The lesions are symmetrical, discrete, deep, and thickly scattered, and consist of primary macules and papules with secondary scratch marks and crust formation. The symptoms are intolerable itching and burning, especially after bathing or retiring for the night.

In the differential diagnosis, scabies must be ruled out. This was carefully done in all cases. The

---

[1] Vokoun, F. J.: Linseed Oil Dermatitis, Ohio State M. J. 23: 229 (March) 1927.

Wassermann test should also be employed to rule out a possible atypical secondary rash. If the diagnosis is difficult, a simple test will prove it: Have the men stay away from work for a few days, and they will improve if their dermatitis is due to the oil.

In my experience sulphur ointment, calamine lotion, 5 per cent white ammoniated mercury and Lassar's paste have failed to give relief in severe cases. The only thing to do for these sufferers is to grant them a "vacation" until their epidermis becomes intact.

CONCLUSIONS

1. Dermatitis is very common among the workers in linseed oil mills.
2. The areas affected are those which come in contact with the oil, this being an example of dermatitis venenata.
3. The cases occur more frequently when Indian or South American seed is being pressed than when Canadian or American seed is used, so that it may be assumed that the irritating substance is in larger proportion in the former seeds.
4. The exact nature of the irritating substance is at present undetermined.

ACUTE CARDIAC DILATATION

AN EVER PRESENT DANGER IN INTRAVENOUS INJECTIONS *

J. H. CLARK, M.D.
PHILADELPHIA

A comparatively few years ago, the injection of drugs into the circulation was considered a somewhat dangerous practice and as a daily procedure was viewed as radical therapy. Today, however, it has become a well recognized therapeutic method of administering drugs, and almost everything in the Pharmacopeia is prepared in ampule form for intravenous use. The procedure is not, however, unattended with danger. Even simple intravenous injections of supposedly innocuous physiologic sodium chloride solution or dextrose in saline solution may prove disastrous, if the cardiac condition of the patient is considered of secondary importance to the accepted intravenous therapy or his general condition. The practice has become so prevalent that intravenous injections of saline or dextrose solution are employed, almost as a routine measure, even in the presence of a failing myocardium, when the patient's general condition appears to be failing or he is in need of fluid which cannot be taken by mouth. The bad and possibly fatal effect of the extra load thrown rapidly on the heart is lost sight of in the attempt to give the patient the required fluid or antiketogenic substance.

Recently, at the Samaritan Hospital, we have had two deaths occurring in patients shortly after intravenous injections of 10 per cent dextrose solution, and one after physiologic sodium chloride solution (charts 1, 2 and 3). Of the two patients receiving dextrose solution, each experienced chills about twenty minutes after the injection. Their pulses became irregular and feeble, and they died within four and nine hours after the injection. One had received previous injections of dextrose solution without exhibiting such phenomena.

REPORT OF CASES

Case 1.—A woman, aged 39, had auricular fibrillation before the performance of a cholecystostomy for gallstones, Nov. 29, 1926. Her immediate postoperative condition was good. The wound drained well, and there was slight arrhythmia after operation. December 1, the patient received 500 cc. of a 10 per cent dextrose solution intravenously without reaction. This was repeated, December 2, and again, December 3, without reaction. The patient's general condition improved. December 4, at 2 p. m., immediately following an intravenous injection of 10 per cent dextrose solution, the patient had a chill of twenty minutes' duration, and complained of severe pain in the region of the heart and of a sense of oppression. She became progressively more cyanotic and expectorated continuously small quantities of whitish fluid (edema of lungs?). The pulse was irregular and scarcely perceptible. Death occurred at 11 p. m.

Case 2.—A man, aged 35, had a vesiculostomy and prostatectomy performed, Dec. 9, 1926, for purulent vesiculitis and perirectal phlegmon. He developed hiccup and vomiting. The blood pressure fell from 120 systolic and 65 diastolic to 60 systolic and 30 diastolic, December 13. On this date at 10:50 p. m. the patient was given 475 cc. of a 10 per cent dextrose solution intravenously. Chill developed at 11:10 p. m., the patient became cyanotic and despite stimulation died at 2:40 a. m., December 14.

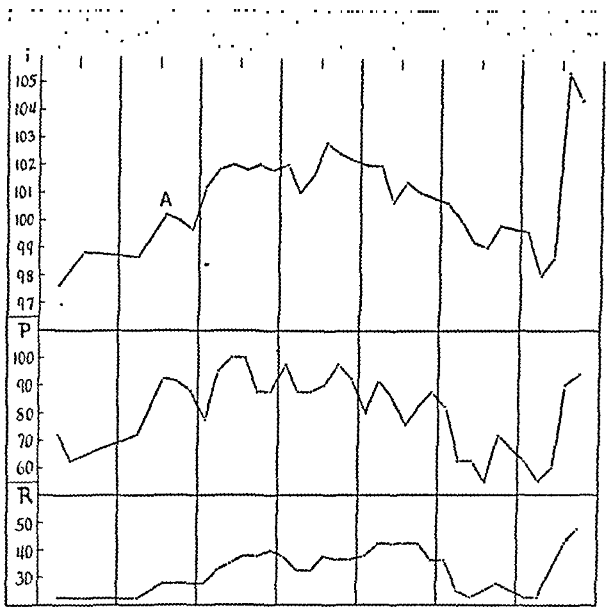

Chart 1.—Temperature, pulse and respiration in case 1: *A*, after operation.

Case 3.—A girl, aged 9 years, at midnight, Feb. 7, 1927, had an appendectomy performed for a gangrenous appendix. Her immediate postoperative condition was good. February 8, she received 250 cc. of Fisher's solution by bowel. Februry 9, vomiting developed. The patient was given 500 cc. of a 2 per cent dextrose solution by hypodermoclysis at 12:45 p. m. At 4:45 she received 425 cc. of physiologic sodium chloride solution intravenously through a small hypodermic needle. At 5 o'clock the patient became cyanotic; breathing was labored; the pulse was rapid and thready, and a chill developed, lasting one-half hour. Venesection was attempted at 6:05 but without result, as the veins were collapsed. The patient died at 6:22 p. m. from acute cardiac dilatation.

COMMENT

At our clinical pathologic conference, it was suggested by some that these deaths might be due to some impurities in the dextrose solution, to alterations in the molecular constitution produced by sterilization, or to the formation of by-products on standing. However, all the dextrose solution used for intravenous work at the Samaritan Hospital is prepared daily in 500 cc. flasks from dextrose U. S. P., and what is not used on the day of its preparation is discarded. Checking over the histories of patients in the hospital who received intravenous injections of dextrose on the same date, we could not find any similar reactions. This seemed to rule out the possibility of dextrose being responsible. However, that a personal idiosyncrasy to dextrose in case 2 might exist must be kept in mind. Hanzlik and Karsner,[1] in an experimental study of anaphylactoid phenomena, concluded that intravenous injections of sucrose in hypertonic concentrations of 50 and 85 per cent are moderately though definitely injurious to the lungs, although symptomatically they appear to be indifferent. They did not, however, include dextrose in their study, and the results are not, therefore, directly applicable to dextrose, although suggestive.

---

* From the laboratory of the Samaritan Hospital.

On the other hand, Hewlett[2] states that "a dilatation of the ventricle may be caused either by a weakening of the muscle with a lessening of the ventricular tone or by an increase in the demands on the heart." In patients whose hearts have already been subjected to nervous or toxic trauma, by operation or toxemia, both factors are at work, particularly when comparatively large quantities of fluid are thrown directly into the circulation in a short period of time. He states further that:

> A temporary increase of work leads to a further but temporary increase in the size of the heart, which within limits aids the cardiac contractions. If, however, the acute dilatation exceeds a certain limit it may exert a very unfavorable effect upon the cardiac function. Excessive dilatation lessens the contractile force of the muscle and the changes that characterize acute cardiac failure then supervene. The dilated ventricle fails to expel the blood coming to it, the venous pressure rises, and this in turn tends to distend the ventricular cavity still further during diastole. . . . If, however, the demands are not reduced below the functional capacity of the weakened muscle, the continued collection of blood in the dilated ventricle leads to a cardiac death.

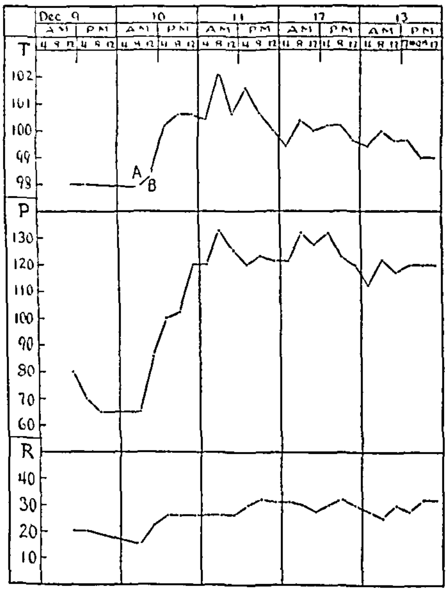

Chart 2.—Temperature, pulse and respiration in case 2: *A*, before operation; *B*, after operation.

This, it seems to me, is what happens when intravenous infusions of physiologic sodium chloride solution or 10 per cent dextrose solution are administered to patients already showing cardiac impairment, as evidenced by a weak rapid pulse.

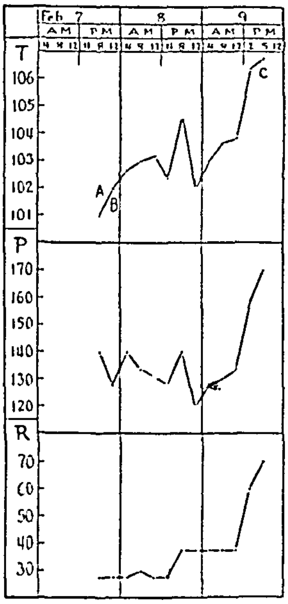

Chart 3.—Temperature, pulse and respiration in case 3: *A*, before operation; *B*, after operation; *C*, by rectum.

Another death occurring on the outside, as detailed to me by the assistant of the attending physician, illustrates quite clearly the cardiac death described by Hewlett. The patient, a victim of abortion, showed definite toxic signs and symptoms, and an intravenous injection of 500 cc. of 10 per cent dextrose solution was ordered. This was administered slowly by gravity, through a small caliber needle. After about 250 cc. had entered the circulation, the pulse improved in both regularity and volume, although no blood pressure determinations were made; the patient stated that she felt improved and she appeared brighter and stronger. The intravenous injection was continued until the total amount of 500 cc. had been given. The temporary improvement, however, noted after 250 cc. had been administered, was replaced by the former weak, thready condition of the pulse, and the patient died shortly after the infusion. Acute cardiac death is also illustrated by case 3. The solution was given through a hypodermic needle, and, while probably not given too rapidly, nevertheless caused serious embarrassment to the heart, for the patient became dyspneic and cyanotic after 425 cc. of physiologic sodium chloride solution had been given intravenously and died about one and a half hours later. Venesection was attempted to relieve the cardiac dilatation, but without results. Again in case 1, although bedside notes were not made by the physician or intern regarding the condition of the lungs by auscultation, or of the blood pressure, the continuous expectoration of small amounts of a whitish fluid, after the injection, is extremely suggestive of a pulmonary edema and failing right heart, aided, at least, by the additional fluid given intravenously.

CONCLUSION

Intravenous therapy is not the innocuous procedure it is generally considered, and these four cases illustrate the necessity of carefully choosing patients for the intravenous administration of drugs, particularly when large amounts of fluid are to be given. If the injection is given slowly and a careful watch is kept of the pulse and cardiac condition, by frequent blood pressure determinations made during the injection, such fatalities should be preventable.

REPEATED ACIDOSIS AND COMA IN JUVENILE DIABETES *

THOMAS A. CLAWSON, Jr., M.D.
AND
GEORGE A. HARROP, Jr., M.D.
BALTIMORE

The eventual prognosis in patients with juvenile diabetes has aroused great interest recently, since it has become quite evident that modern methods of treatment are of especial value in this type of the disease. It has been frequently emphasized that diabetes in childhood and in youth is usually uncomplicated by any of the numerous extra factors that may be present in later life. Diabetic children in the absence of severe infection usually respond very readily to dietary measures and to insulin, and severe acidosis or coma, in general, is quite as amenable to treatment as it is in older patients in whom diabetes is generally considered to be less severe. Recent articles by prominent American students of the disease (Joslin, Geyelin) indicate that the experience gained in the study of large series of cases since the introduction of insulin gives just cause for a considerable measure of optimism. In sharp contrast to this point of view are the conclusions reached by recent German observers,[1] who are decidedly pessimistic. Doubtless it is entirely too soon to expect definite conclusions as regards this difficult problem. It should be borne in mind that reliable and standardized insulin preparations were available for use on the continent much later than in this country.

That proper medical direction and the constant and intelligent obedience to instructions are in any event indispensable for the successful management of patients with juvenile diabetes we believe is well shown in the accompanying case report, which records twelve successive periods of severe acidosis or coma in a colored child, following dietary indiscretions, and, in one instance, of infection. Death finally resulted outside the hospital, evidently in coma, because the family did not apply for medical aid.

REPORT OF CASE

B. W., a colored girl, aged 11 years at the time of the first admission, Jan. 29, 1924, to the Johns Hopkins Hospital in diabetic coma, had become suddenly ill about six weeks before, with polyphagia, polyuria and polydipsia. It was noted that she tired very easily and that there was gradual loss of weight. Her past history was not significant: pertussis at 3 years, measles at 5 years and two attacks of tonsillitis at 7 and at 8. There had not been any other infections. The family history did not include any cases of tuberculosis obesity, diabetes or obvious endocrine disorder. During the following thirty-four months, until death occurred outside the hospital, Nov. 26, 1926, she was admitted twelve times in severe acidosis or coma, and in all spent 549 days out of the intervening 1,131 days in the ward. Death finally occurred owing to the fact that she was not brought to the hospital for treatment following a dietary excess on Thanksgiving Day, 1926. All the attacks were severe, but the patient responded with relative ease to treatment in each of them. The dietary lapses were in all instances primarily due to neglect. Either the child was allowed to shift for herself at home or she stole food or candy because supervision at home was completely lacking. Strenuous efforts were continuously made by the social service department of the hospital to secure some measure of cooperation, or permission to place the child in a home where proper care would be assured. Unfortunately, it was impossible to do anything that would be permanently satisfactory. The accompanying table gives the salient facts recorded during the course of the disease.

Course of the Disease

Admission	Date of Admission	Condition	CO_2 Capacity (Van Slyke) per Cent by Volume	Probable Cause from the History	Date of Discharge	Diet on Discharge				Insulin Dosage on Discharge, Units	Growth Under Observation	
						Carbohydrate	Protein	Fat	Calories		Height, Cm.	Weight, Kg.

Died unattended outside the hospital in coma, due to dietary excess and lack of insulin, Nov. 26, 1926.

COMMENT

Aside from the unusual history of this patient, we believe that the case presents certain points for reflection. An inspection of the summarized table makes it evident that the diabetic condition gradually became more severe with each period of hospital observation. The carbohydrate tolerance in proportion to the insulin requirement grew progressively worse. We do not believe, however, that this is a fair indication of what might have been the course under proper treatment. The social conditions in which the child lived could scarcely have been worse, and the parents were almost completely devoid of intelligence or insight into the situation. We think that the fact that so many shocks and insults were withstood in so short a period, and that relief from severe acidosis or coma was repeatedly obtained so easily, indicates that under a more favorable environment a happier outcome might have been anticipated.

In the face of unreasonable resistance and lack of cooperation on the part of those responsible for the care of a diabetic child, it is very unfortunate that steps cannot be taken to commit the patient during the period of minority to an institution where proper care and dietary treatment might be given. We estimate that the cost to the Johns Hopkins Hospital of the periodic and perfectly futile rehabilitation of this patient, in large measure unnecessary under other circumstances, and exclusive of medical attendance, was about $2,500. Juvenile diabetes is not a very uncommon disease. This case is an unusually striking instance of several such cases which we have seen in this clinic in the indigent poor, and no doubt the same situation holds good in every large diabetic clinic. The continuous free supply of insulin to these patients, who often require large daily doses, is a serious financial burden. It is unfair to expect the medical outpatient departments of hospitals to assume this obligation indefinitely. It could properly be undertaken by public health authorities in the same way that biologic serums and antitoxins are rendered available, and the necessary and essential continuous medical supervision might properly be assumed by the same agency. That it will assuredly be necessary to work out some such public system of relief would seem certain.

THE NASAL APPLICATION OF SOLUTION OF PITUITARY FOR OBSTETRIC PURPOSES

PRELIMINARY COMMUNICATION

J. ISFRED HOFBAUER, M.D.
BALTIMORE

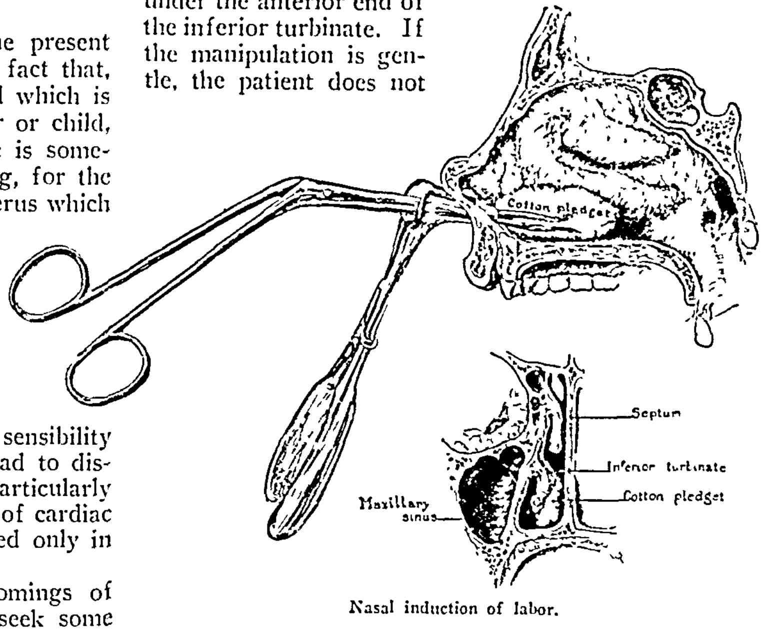
The recent clinical study of Scott on the present state of the induction of labor revealed the fact that, up to this time, no method has been devised which is altogether free from danger to either mother or child, and more particularly that Watson's technic is sometimes followed by death of the infant, owing, for the most part, to the tetanic contraction of the uterus which sometimes follows the use of solution of pituitary. Watson's method is based on the sensitization of the uterine muscle by the administration of castor oil and quinine, followed by the subcutaneous injection of 0.5 cc. of solution of pituitary at half hour intervals, until labor sets in or until six doses have been given. Those who have had experience with the method agree that undue sensibility to the action of solution of pituitary may lead to disastrous effects on the child; and as this is particularly likely to occur in the presence of toxemia or of cardiac complications, the method should be employed only in selected cases.

The general recognition of these shortcomings of Watson's method gave me the impetus to seek some method of improving it. Two main considerations guided my search for new channels through which solution of pituitary may be administered in a more effective and at the same time in a less dangerous way; the desiderata being to discover, if possible, whether its local application to some mucous membrane would permit its slow and steady absorption, and, if this were the case, to permit the possibility of withdrawing the drug as soon as the tendency of the uterus to pass into tetanic contraction became noticeable.

The oral administration of solution of pituitary was first considered, since the recent experimental work of Knaus showed that after the administration of the drug to the sublingual region a marked increase in the tone and automatic movements of the uterus occurred. We employed this technic in twenty patients, and labor was successfully induced in nine of them, an efficacy of 45 per cent. In eleven additional instances the sublingual application was employed to stimulate pains in women already in labor, but in whom the pains had stopped for a number of hours, irrespective of the degree of cervical dilatation and regardless of whether the membranes were ruptured or not, and satisfactory results were obtained in ten patients without ill effect to either mother or child.

In the search for another portal of entry from which the solution of pituitary could be absorbed more satisfactorily, my attention was directed particularly to the nasal mucosa, in view of the fact that the mucous membrane covering the inferior turbinate is a highly vascular tissue, whose blood and lymphatic supply is markedly increased during pregnancy. Since in the present communication I propose to deal chiefly with the therapeutic utilization of the nasal mucosa for the absorption of solution of pituitary, both through the blood stream and by way of the lymphatics, the accompanying semidiagrammatic representation of the lateral nasal wall will be of service in understanding the topography.

Under direct vision, with aid of a nasal speculum and reflected light, a small pledget of cotton of such size as to fit easily but snugly between the septum and the inferior turbinate, and moistened with from 10 to 20 minims (0.60 to 1.25 cc.) of solution of pituitary is inserted under the anterior end of the inferior turbinate. If the manipulation is gentle, the patient does not experience any appreciable discomfort, and in none of our cases was it necessary to resort to any kind of local anesthesia.



Nasal induction of labor.

Prior to the nasal application of solution of pituitary, the patient is prepared in the routine manner by being given a hot drink and castor oil and quinine by mouth, followed by a high enema. From two to three hours were then allowed to elapse before the administration of the first dose of solution of pituitary, in order to make sure that the preliminary treatment had not been sufficient to induce pains. Uterine contractions invariably follow within from three to five minutes after the nasal application. In the event that the first contraction lasts longer than four minutes, the pledget is withdrawn when the uterus relaxes within the next sixty or seventy seconds. If, however, tetanic contraction does not occur during the first fifteen minutes, it is considered that all danger from such an accident has passed.

Unless the first application has resulted in setting up satisfactory contractions, the pledget is withdrawn at the end of two hours, and a fresh one applied to the opposite nostril for a similar period of time. In the majority of my cases, from one to three applications were required for a successful induction of labor, but in a very few cases as many as five doses were necessary. It is important to bear in mind that experience shows that in preeclamptic cases labor can be induced with the greatest ease, one application of solution of pituitary usually being sufficient; whereas greater difficulty is encountered in the nephritic cases, in which the response is definitely less pronounced. It is interesting to note that in none of the toxemic cases did the blood pressure rise materially over the initial level during the course of induction. Furthermore, I gradually came to realize that while in normal pregnancy the nasal method is rarely effective much before term, it gives satisfactory results in toxic patients a month or six weeks earlier.

Up to the present, we have employed the nasal method of inducing labor in seventy patients; the indications are given in the accompanying table.

Indications for Nasal Application of Pituitary Extract

1. Toxemia	28 cases
2. Postmaturity	12 cases
3. Severe pyelitis	5 cases
4. Hydramnios	2 cases
5. Dead fetus	2 cases
6. To test the method in normal pregnant women during the last month of pregnancy and at term	21 cases

In groups 1 to 5 (forty-nine cases), labor was induced successfully in every instance. On the other hand, nine failures occurred in the sixth group. Here it was found that when the cervical canal measures 2 cm. or more in length, and the external os is tightly closed, the chances of success are comparatively poor; while the prospects are much better when the cervical canal is obliterated. This observation is quite in harmony with the results of Knaus' recent experiments, which indicate that considerable changes occur in the relationship between the hypophysis and the uterine muscle during pregnancy, and that as a result of an increase in the sensitiveness and the tone of the uterine muscle toward the end of pregnancy, labor can be induced in animals by comparatively small doses of solution of pituitary at term, although such doses are entirely ineffective before term.

The fact that in this series all the babies were born alive testifies to the control one possesses over the action of the drug. Furthermore, it may be mentioned that the nasal method has also been found a safe and efficient procedure for accelerating labor already in progress.

A more extended paper on the subject by me and my co-workers, Drs. Hoerner and Oliver, will shortly appear in the *American Journal of Obstetrics and Gynecology*.

Johns Hopkins Hospital, Washington and Monument streets.

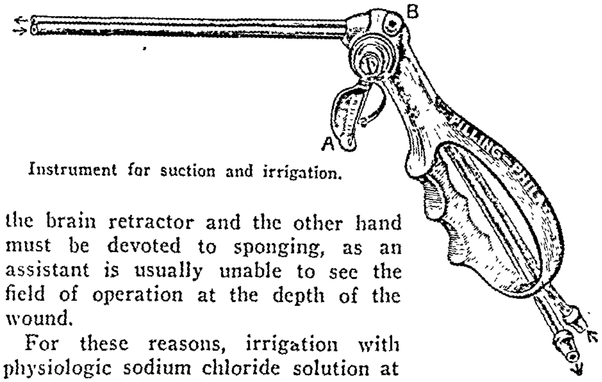
Clinical Notes, Suggestions and New Instruments

A NEW INSTRUMENT COMBINING SUCTION AND IRRIGATION FOR INTRACRANIAL SURGERY

Temple Fay, M.D., Philadelphia
Neurosurgeon, Episcopal Hospital; Associate in Neurology, University of Pennsylvania School of Medicine

The need for clear vision in the depth of a small field is well recognized by every neurosurgeon. Operations on the brain and spinal cord must be performed within a very limited area, such as the transfrontal approach to the pituitary body, the section of the posterior root of the trigeminus, and certain suboccipital operations involving the cerebellopontile angle.

The lighted retractor has proved invaluable in exploring these deep recesses below the brain. The great problem at present concerns the matter of sponging within the depths of the wound, so as to give a clear view of the structures and landmarks presenting during the operation. The extreme friability of the cortical vessels has made it necessary to use the softest cotton pledgets, small enough to be introduced into the limited space concerned. A small amount of hemorrhage in the depth of the wound arrests the progress of the operation until the bleeding point has been controlled. The use of many of these cotton sponges is necessary to remove even a small amount of blood. There is frequently the danger of leaving a small cotton pledget behind. The operator is often at a distinct disadvantage, because one hand is occupied by the brain retractor and the other hand must be devoted to sponging, as an assistant is usually unable to see the field of operation at the depth of the wound.



Instrument for suction and irrigation.

For these reasons, irrigation with physiologic sodium chloride solution at a temperature of 100 C., followed by suction as a means of clearing the field, has become of extreme value. Heretofore this method has been one of alternate irrigation and suction, and the operator has found it difficult to employ the proper procedure with sufficient rapidity to locate a small bleeding point. The instrument here illustrated has overcome this difficulty in that it combines both suction and irrigation, permitting the operator to direct accurately the flow of warm saline solution to the proper point, and withdraw the accumulating fluid as rapidly as necessary. The instrument is so designed that it may be used for irrigation alone or suction alone, if so desired, or, if suction and irrigation are required at the same time, this may also be accomplished.

The instrument is so balanced as to fit the hand with a pistol grip, the balance being entirely within the palm of the hand, so that the slightest movement of the point can be directed by the wrist. There is no danger of injuring structures because of an unwieldy instrument. The double barreled tip has been made of soft metal, so that it may be molded into any shape or direction that is desired, and the instrument can thus be used to reach inaccessible corners, or to follow the line of operative approach. The spring valve trigger (*A*) controls the irrigation of saline solution. It is so constructed that the valve remains closed until the trigger is pulled. The flow and amount of fluid delivered at the tip depends on the degree of opening of the valve. The height of the fluid container determines the pressure under which fluid is delivered. The "Tucker valve" (*B*), devised by Dr. Tucker in the Bronchoscopic Clinic of Dr. Chevalier Jackson, for suction and control within the depth of the lung, has been utilized in this instrument.

Placing the thumb over the hole in the suction valve (*B*) produces suction at the tip of the apparatus. When the thumb is removed, the air enters valve *B* and there is no suction at the tip. Thus, by a simple movement of the thumb, suction may be obtained. By the flexion of the index finger, irrigation to the desired amount is controlled. The instrument is so constructed as to give the possibility of combined suction and irrigation; and in dealing with hemorrhage from small vessels within the depths of the wound, the bleeding point may frequently be located by the reddish, smoky column arising from a given point, indicated within the body of the clear saline solution, illuminated by the lighted retractor. A muscle graft placed over the bleeding point will give the required hemostasis.

The added advantage of combined irrigation and suction is evident by the fact that the irrigation fluid is within a closed system coming by means of a sterile tubing from a closed water bath reservoir, suspended above the level of the operating table. The suction apparatus, which consists of a simple water pump connected to the ordinary water supply with an intervening container, withdraws the hemorrhage and discolored saline solution from the field. It eliminates the "sloppy" disadvantage of open irrigation and does much to produce a clean, dry field.

In laminectomy work this instrument has proved of decided value in preparing the field before the dura is opened. The muscle bed is repeatedly irrigated with warm physiologic sodium chloride solution. Frequently, many oozing points are thus controlled. The others may be located and carefully ligated. When the irrigation solution returns clear, the dura may be opened without danger of blood from the margins of the wound entering the spinal canal or obstructing the field.

The instrument has been constructed for me by George P. Pilling & Sons Company, Philadelphia, and can be obtained through their offices.

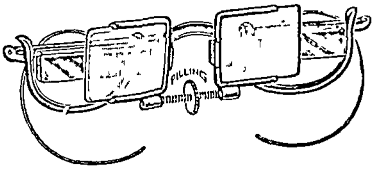
2025 Walnut Street.

FOLDING LOUPE

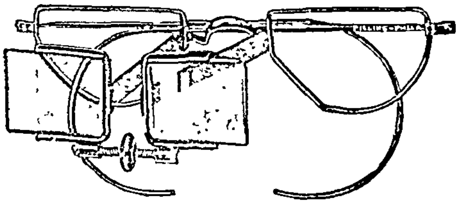
William W. Goldnamer, M D , Oakland, Calif.

Perhaps the most frequently used instrument of an ophthalmologist is a good binocular loupe.

Frequently it has been my misfortune not to have a loupe with me when away from the office, since I could not ordinarily carry one because of its bulk, as all loupes with which I was acquainted were very bulky. So I had alterations made on a Beebe loupe which would not add to its weight (this loupe was fitted with my correction). The loupe will fit in an ordinary number 5 spectacle case.



Loupe folded.



Loupe extended.

The obvious advantage of this will be instantly apparent to any ophthalmologist or to other physicians who need such an instrument.

The makers of this instrument, George H. Pilling and Son Company, Philadelphia, will be able to supply these folding loupes.

577 Fourteenth Street.

Special Article

THE QUARTERLY CUMULATIVE INDEX MEDICUS

WHAT IT STANDS FOR AND HOW TO USE IT*

FIELDING H. GARRISON, M.D.
Lieutenant Colonel, Medical Corps, U. S. Army
WASHINGTON, D. C.

During the year 1926, by arrangement between the American Medical Association and the Carnegie Institution of Washington, it was decided to fuse the *Index Medicus* (1879-1926) and the *Quarterly Cumulative Index* of the American Medical Association (1916-1926) to form the *Quarterly Cumulative Index Medicus,* financed jointly by the American Medical Association and the Carnegie Institution of Washington, compiled from material indexed and classified in the Libraries of the Surgeon General's Office (Washington) and the American Medical Association, and published by the American Medical Association. The new journal will be issued quarterly and cumulated semi-annually in two volumes. The first quarterly number (January-March) appeared in May, 1927. In acquainting our readers with the detailed merits of the new quarterly, it is fitting to give some account of its parentage.

PEDIGREE OF THE PARENT JOURNALS

The *Index Medicus* was started in January, 1879, by Drs. John S. Billings and Robert Fletcher as "a monthly classified record of the current medical literature of the world." This journal might be described as the grandchild of two ideas. Its parent, the Index Catalogue of the Surgeon General's Library, did not become known to the world as such until a year later (1880).

The germinal ideas were conceived in the brain of Billings when he was wrestling with his graduating dissertation on epilepsy at the Medical College of Ohio (Cincinnati, 1861), viz, "to establish for the use of American physicians a fairly completed medical library, and in connection with this to prepare a comprehensive catalogue and index which should spare medical teachers and writers the drudgery of consulting ten thousand or more different indexes or of turning over the leaves of as many volumes to find the dozen or so references of which they might be in search." In making a tabulation of seventy-four ascertainable cases of operations for epilepsy as the material for this dissertation, Billings found himself hard put to it for references and literature, which he obtained with the greatest difficulty, even by correspondence with the medical libraries of New York, Philadelphia and other American cities. He was driven to the conclusion that "while there was nowhere in the world a library which contained all medical literature, there was not in the United States any fairly good medical library" containing even a respectable fraction of this literature. In 1861, in fact, American research workers in medicine, if any, were driven to the several libraries in the European cities.

Billings found his opportunity on the last day of 1865 when, after arduous service as operative surgeon and medical inspector in Grant's campaign of 1864, he was assigned to the Surgeon General's office with nominal care (in addition to other duties) of the small collection of medical books which had existed in the War Department bureau since the days of Surgeon General Lovell (1818). How he gradually built up this collection (2,253 volumes in 1865) during the thirty years of his librarianship, first with the aid of a slush fund, then by annual appropriations from Congress, up to the 116 847 books and 191,598 pamphlets in the Library when he was retired from active service in the army (1895), is another story

---

* Published by permission of the Surgeon General, U. S. Army, who is not responsible for any opinions or conclusions expressed herein.

During the fifteen years preceding the appearance of the first volume of the Index Catalogue (1866-1880), Billings was experimenting on all known methods of cataloguing and indexing medical literature, from the ordinary type of author entry to the Dewey system (1876) Subject entries, fitful and eclectic as those in the catalogue of the British Museum, begin to appear in his catalogue of 1871 (13 330 volumes) and by 1876, he had evolved and published his Specimen Fasciculus of a medical library catalogue, indexing itself, as to both authors and subjects Shortly after this event, Billings acquired an able and loyal assistant in the learned Dr Robert Fletcher, who was assigned to duty in the Surgeon General's Library Sept 1, 1876 As plans for the publication of the Index Catalogue approached fruition, it became apparent to the two editors that while such a publication might give the bulk or cream of the world's medical literature on each indexed subject (say Brain or Cholera or Labor) up to the date of publication of the particular lettered volume (B, 1881; C, 1882, L, 1886), there was need for a current periodical index of the newer medical literature of each successive year The *Index Medicus* was therefore issued in monthly numbers in 1879, while largely through the good offices of Dr Abraham Jacobi, appropriations for printing the first volume of the Index Catalogue were obtained in the same year

The two germinal ideas specified were not essentially new the merit lay, in Captain Cuttle's phrase, "in the application" The oldest known medical publications on Babylonian baked bricks or Egyptian papyri, not to mention the Hippocratic Canon, are really the shreds and remains of virtual medical libraries, works by different hands, associated with the name of an individual teacher, school or period, often overlaid with superadded material The physicians of the Coan and Cnidian schools, as well as Aristotle, Theophrastus and the Alexandrian teachers, undoubtedly had medical libraries The probable or presumable libraries of physicians in the successive centuries *of the Middle Ages may be readily inferred by* statistical computation of the number of citations from old authors in the various medical MSS or incunabula In her classification of the 15,000 medical MSS of the Middle Ages extant in Great Britain, Dorothea Singer has, in fact, given us the probable subject classification of a medieval medical library Many of the earliest printed books are carefully indexed from A to Z, nay, some of these incunabula, such as the Aggregator or Matthaeus Salvaticus, are really alphabetical index catalogues of the drugs and simples of the time The concordances of Hippocrates by Erotian, Foes and Littre, or of Galen by Brassavola and Kuhn, are alphabetical subject indexes to whole vast periods of Greek medicine As far as mere books and pamphlets were concerned, Conrad Gesner Merklin, Haller, Ploucquet, Young, Forbes, Atkinson, Watts, Hain, Choulant and Haeser had all made valuable contributions to medical bibliography Haller published exhaustive bibliographies of botany, anatomy, surgery and internal medicine (1771-1778), Haeser of epidemic diseases (1843), Meissner a model index catalogue of books on pediatrics (1850) During 1830-1845, the Danish surgeon, C P Callisen, had even made a kind of index catalogue of the periodical medical literature of 1750-1845, but by authors only

The new feature of the Index Catalogue and the *Index Medicus* was the exhaustive indexing of the books, pamphlets and contents of periodicals alphabetically by subjects, as well as by authors The main classification in the first and second series of the *Index Medicus* (1879-1899) was a somewhat hierarchical arrangement of subjects in order of relative importance, from Bibliography and Anthropology to Nursing and Veterinary Medicine, under which rubrics the books and periodical titles indexed were alphabetized by authors This necessitated the preparation and publication of somewhat cumbersome and expensive author and subject indexes to each annual volume The classification employed in the latter was that of the Index Catalogue Up to 1900, the attractive feature of the *Index Medicus* to university professors and research workers was its appearance in monthly numbers To men like Welch or Osler or Jacobi or Mitchell these afforded, at stated intervals, a purview of their specialties or of the whole field of medicine, as pleasant and arresting as were the morning *Spectator* or *Tatler* to the eighteenth century Englishman At the same time, the annual author and subject indexes insured the usefulness and value of the *Index Medicus* for the future But it was obvious, from the start, that a journal of this type, financed by private enterprise, with a limited subscription list (never exceeding 500) was foredoomed to financial disaster After contributing materially to the bankruptcy of two successive publishers, the *Index Medicus* was financed by its actual editor, Dr Fletcher, at the phenomenal rate of $25 per annum, up to 1899, when it suddenly collapsed from lack of financial support During 1900-1902, an attempt to carry on, with very restricted material, was made in France, under the title "Bibliographia Medica," edited in three successive volumes by Drs Marcel Baudouin, Charles Potain and Charles Richet (Paris) In 1903 the American *Index Medicus* was revived by the Carnegie Institution of Washington, which published the Second Series (vols I-XVIII, 1903-1920) and the Third Series (vols I-VI, 1921-1926) During the forty-six years of its existence (1879-1926), the *Index Medicus* comprises forty-five, or, including the French publication, forty-eight volumes

In January, 1916, the American Medical Association published the first number of its *Quarterly Cumulative Index to Current Medical Literature* This journal introduced several important improvements in medical indexing. Like the Surgeon General's Catalogue, the new *Quarterly* indexed itself as to both authors and subjects, furthermore, by cumulation of the first three quarterlies in succession, the last quarterly of each year became, in effect, the completely indexed volume Both author and subject titles were given in English, the former of utmost brevity in the earlier volumes, the latter more expansive The arrangement of the material on the page was the best possible for ready reference, and the exploitation of type had been carefully thought out with regard to perspicuity The new *Quarterly* thus became immediately popular among research workers and reference librarians Here, in fact, was a new departure and along lines for which the world had long waited, viz, an automatic system of self-indexing, which dispensed with the cumbersome index to an index, whether of authors or subjects or both The gain in checks on accuracy through the full time service of a large personnel was also of moment. The only drawback to the new publication was the relatively small number of periodicals indexed, 157 in 1916, 326 in 1926. The A M A *Quarterly* made the strongest appeal for current usage The *Index Medicus* had, as covering all the material, the optimum survival value for the future At the same time, it became obvious to all interested that there was an enormous duplication of labor, effort, administration expense, paper, printers' ink and consumption of time in the preparation and publication of two large and costly periodicals covering much the same ground The manifest destiny of the two journals was fusion, but even tentative consideration of this idea was out of the question after the event of April 6, 1917, when both the American Medical Association and the Carnegie Institution of Washington became immersed in wartime activities

ADVANTAGES OF FUSION

The *Index Medicus,* in the wording of Army Regulations, "is not a governmental document" but a periodical supplement to the Index Catalogue, and was prepared for the press from the start as an extra-official activity The entries were copied from the library cards by outside people, the redaction of copy and proofreading of the journal and its indexes were done by the editors as night work outside the Library. In the early days of the eighties and nineties, the monthly numbers seldom averaged more than 50 or 60 pages, the volume (say in 1894) covering about 600 pages or about 12,000 to 15,000 titles. By "sporting oak" and denying himself to visitors, it was possible for Dr. Fletcher to run off a monthly number for the printers in a single evening. With greatly restricted material, the French Index Medicus of 1900-1902 covered 974, 1,128 and 888 pages, respectively. In 1903, the revived *Index Medicus* covered 1,065 pages, exclusive of the author and subject indexes; in 1913, 1,448 pages; in 1914, 1,311 pages. The cost of the journal since 1903 has thus been always considerably in excess of the liberal annual grant made by the Carnegie Institution of Washington. This question of extra expense became of moment in 1913, but the situation was saved by the European war, which greatly cut down the output of worthwhile medical literature in the warring countries, while, during the lean years following the war, the exclusion of the trashier sort of literature which then abounded was a genuine public service. At the same time, this extraordinary proliferation of periodical medical literature, amounting to more than twice the quota of 1894, vastly increased the probabilities of error in copy and proofs, while the reliable personnel employed was decreasing annually through death or other unavoidable contingencies. In 1921, owing to the impossibility of acquiring suitable personnel to carry on the annual Subject Index, the old subject arrangement of 1879-1920 was discarded, and the *Index Medicus* began to index itself quarterly as to subjects (in alphabetical order). The expensive and cumbersome Author Index was perforce retained. The American Medical Association, meanwhile, possessed the advantages of numerous and efficient personnel, rapid and effective press work, and administrative facilities for making the combined Index more widely useful and continually valuable.

THE COMBINED JOURNAL

In addition to indexing itself alphabetically as to authors and subjects, the salient features of the new index are that (1) it combines the best features of the classification of the *Index Medicus* and the *Quarterly Cumulative Index;* (2) the author titles are now given in full in the original languages, with the exception of titles in the Slavic, Scandinavian and Oriental languages, which are presented in English translation; (3) the subject entries are brief English abstracts of the actual content of the articles in question, without references to the titles, unless the latter happen to be accurately descriptive. It is the hope and belief of the editors that, in the long run, the latter device will awaken medical authors and editors to the advantage and necessity of providing all articles in medical periodicals with accurate descriptive titles, since papers of real import and value are submerged and actually lose themselves under titles which are ambiguous, obscure or misleading. In aid of this matter, the classification-rubrics are chosen with the greatest care, again, with reference to the actual content of the articles, and these arrangements are further helped out by a liberal system of cross references, which was not possible in the *Index Medicus.* The new books of the quarter are presented, for ready reference, both by authors and by subjects and with prices attached, on page 2 of the new Index. There follow an alphabetical list of publishers of the books and periodicals indexed (American and foreign) and an alphabetical list of all the periodicals indexed, with full titles, names and (where possible) addresses of publishers. The number of current periodicals now coming into the Surgeon General's Library is about 1,925. They include all important periodicals of anthropology, biology, psychology and even those of chemistry, physics and general science which may publish articles bearing on medicine. Any unusual and worth-while books or articles of this character not apt to be featured through regular medical channels will be included if sent to the Chicago editor (American Medical Association).

MODULUS OF CLASSIFICATION

Beginning with 1879, the nomenclature and classification of diseases employed in the Index Medicus was that of the Royal College of Surgeons, derived, in turn, from the classification proposed by William Farr[1] in 1855. Naturally subject to many changes and additions incident to advances in modern medicine, this arrangement has stood the test of time. Its immense superiority over the older "botanical" arrangements, listed by Wunderlich in the appendixes to his History of Medicine, will become at once apparent to any one familiar with the classification of diseases (say) in the tenth edition of Osler's Practice, which really derives from Farr. In these days of interrelationship of all the applied sciences, in which even anthropology is in process of transformation through advances made in medicine, the proper classification of many complex titles of newer type becomes a matter of extreme difficulty or even delicacy. As only one entry of such titles could usually be made in the Index Catalogue or the *Index Medicus,* it became necessary in each case to find the center of gravity of the title, and this modulus of classification, like other moduli, was quantitative, i. e., had to turn on actual or apparent weight (some preponderant feature) in the scale of relative importance. Thus, articles on the oculocardiac reflex or the effort syndrome (D. A. H.) or "Latent Cerebral Tumor in a Case of Epilepsy Treated by Luminal," found their places automatically under Reflex *(Oculocardiac),* Heart *(Neuroses)* or Epilepsy *(Pathology).*

In the *Index Medicus,* because of the high cost of printing, no cross references to the collateral subjects could be made. In the new *Quarterly Cumulative Index,* however, titles of this type, if sufficiently important, are actually duplicated or triplicated under the collateral rubrics, which makes fuller bibliographies under important headings. When not employed as title-rubrics in the new journal, the Index Catalogue rubrics of the Washington classification are protected by ample cross-references. For classifiers of medical literature, perhaps the most bothersome, boresome and baffling titles are those in which two or more seeming disparates, (such as cancer and tuberculosis) are linked together. The general formula of this abundant class ("something-or-other and something else") is as laughable in its stereotypy as the pattern which was put to such liberal usage in novels of the Damnation-of-Theron-Ware type. In the *Quarterly Cumulative Index,* which employs not one but several moduli of classification, the difficulty attaching to these double-barreled titles is obviated by printing them under both disparates or otherwise covering one disparate by a cross-reference. Thus, in the January-March number of the new journal, the article by Adamantiadis will be found under "Trachoma" and "Keratitis," that by Agnoli under "Diabetes, Insulin in," and "Diuresis," with reference to the former from "Insulin," that by Albrecht (O.) and Ranzi under "Achondroplasia" and "Spinal Cord Compression."

HOW TO USE THE NEW INDEX

For research workers, the classification of the *Index Medicus* of 1879-1926 is identical with that of the Index Catalogue. In other words, references to the total medical literature of the years 1879-1920 will be found in the annual subject index of the *Index Medicus* for these years, and in the self-classifying arrangement of the four quarterly numbers for the period 1921-1926. The same thing applies to the *Quarterly Cumulative Index* of the decade 1916-1926, for the limited number of periodicals covered during these years. Beginning 1927, the *Quarterly Cumulative Index Medicus* will cover all the medical and scientific periodicals on hand in the Surgeon General's Library, numbering 1,925. Mercifully for the medical profession, not all these 1,925 periodicals are indexed or deserve to be indexed. An astounding percentage of recent medical literature is piffle. But any worthwhile scientific periodical of today, even of subjects like anthropology, geography, philology or mathematics, may contain an occasional medical article of value, and this kind of indexing will be extended shortly to the scientific and secular periodicals in the Smithsonian Library and the Library of Congress. Foreign book titles are catalogued for the new Index directly from the descriptive trade lists.

How to use all this material? Suppose your subject is the pituitary gland. Look for the literature in its alphabetical place, then follow up, as in the Index Catalogue, with such cross-references as are germane or essential; e. g., Acromegaly, Endocrine Glands, Hypothalamus, Infantilism, Obesity. If it is Hydrogen Ion Concentration, then follow up with Acid-Base Equilibrium, Acidosis, Alkalosis, Blood, Cerebrospinal Fluid, Urine and so on. To get the maximum usage out of the Quarterly Index, familiarize yourself with the essential features of its classification beforehand and follow up all the cross references. Foreign readers who cannot cope with the English titles under the subject rubrics will find the full title in the original language under the author entries. On account of the large amount of 1926 literature on hand during January-April, 1927, the quarterly will not attain its full stride into the 1927 literature until the first cumulative volume is published in July, 1927. This overlapping of material at the beginning of each year is unavoidable, by reason of the large amount of foreign literature which does not reach American libraries until comparatively late in the year. In looking, therefore, for references allocated to a certain year (say 1927), consult the volumes for the given year (1927) and the succeeding year (1928). Successful research depends on the worker as well as on the index. In the words of the late President Woodward of the Carnegie Institution: "The scientific specialist who does not know more of his subject than a bibliographer can teach him is not worth his salt."

ENVOY

The curse of recent medicine is the gigantic, senseless proliferation and prolixity of its periodical literature. It has been the despair of librarians, the enslaver of indexers, the nightmare of classifiers, the bugbear of editors, and, even in Dr. Fletcher's time, was the occasion of his celebrated witticism: "The whole world is in a conspiracy against medical bibliographers." It is a consequence of the self-determination mania which "infects the world" and the end is not yet, for there are as many "new" sciences as there are up-and-coming nations. Some day there may be minor Nobel prizes or *prix Monthyon* for those who decline to write unless they have something really new to say and who can state their intention in titles of telegraphic brevity.

In 1926, as stated, it was decided by the authorities of the three organizations concerned that the *Index Medicus* and the *Quarterly Cumulative Index* were

> This day to be conjoined
> In the estate of honorable marriage.

The natural consequence of lawful matrimony made its appearance within the statutory time, and it is no exaggeration to say that the young hopeful, in the words of our leading humorist, was ushered into the world "to the tune of sweet, soft music. There was no harsh bawling from below. There was dulcet twittering from above." Mayhap there was even "rejoicing in heaven," for, with the retirement of the parents, there was to be one medical journal the less in the world. The *Quarterly Cumulative Index Medicus* represents, as stated, the culmination of an effort, long since contemplated, to save the duplication of expense, labor and time consumed in the production of two large and costly periodicals covering much the same material. As combining the best resources available and as employing the most advanced and labor-saving methods of medical indexing, the new Index deserves, therefore, the hearty and unqualified support of the entire medical profession all over the world. May we auspicate its future in the ancient invocation, *quod felix, bonum faustumque sit.*

Army Medical Library.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

CROTALUS ANTITOXIN.—An antitoxic serum prepared by immunizing animals against the venom of snakes of the crotalus family.

Actions and Uses.—Evidence has accumulated to show that the venom of certain snakes may be neutralized by the employment of a serum obtained from animals that have been injected with venom from a snake of the same family. Crotalus antitoxin is used to neutralize the venom injected by the bite inflicted by members of the crotalus family.

Dosage.—The serum is administered intramuscularly; but in cases seen late or in the presence of severe symptoms it may be administered intravenously.

H. K. Mulford Company, Philadelphia.

Antivenin (Nearctic Crotalidae).—North American Anti-Snake-Bite Serum.—An antitoxic serum prepared by injecting horses with venoms from serpents of the North American species of the family *Crotalidae* (Rattle Snake, 75 per cent; Copperhead, 12½ per cent; and Water Moccasin, 12½ per cent). *It is claimed to have neutralizing* effect against the venom of the species represented. The venom is extracted from the snakes and promptly desiccated. The mixture of the venoms is injected subcutaneously into horses in fractional doses until immunity is established. The animal is bled, and the plasma is concentrated by a salting out process. The potency of the product is determined by tests on pigeons, the maximum amount of venom neutralized by 1 cc. of the serum being taken as the titer of the product.

Marketed in syringes containing 10 cc. (a single dose).

ACTION OF THE PARATHYROID HORMONE

Current writers reflect the conviction that the parathyroid glands produce a hormone that is indispensable to the organism. Its function is sometimes described as that of "mobilizing" the calcium of the body, a statement scarcely more illuminating than the outworn expression "diathesis" as applied to obscure conditions of disease. Probably a more specific description would at present allocate to the parathyroid hormone the regulation of calcium metabolism through the control, in some way, of the concentration of calcium in the circulating blood. The mode in which this regulatory influence becomes effective has been debated, the available evidences being inconclusive at present. The possibilities have been briefly summarized by Stewart and Percival,[1] who state that "clearly the parathyroids may affect the absorption or excretion of calcium, or may exert some controlling action on the equilibria between the different forms of combination in which calcium exists in the blood and between the concentrations in the blood and in the tissues."

The intake factor can be easily disposed of: In view of the ease with which the low serum calcium of tetania parathyreopriva can be raised by administration of calcium salts, it appears unlikely that the parathyroids act by controlling calcium absorption. Furthermore, in the latest experiments at the University of Edinburgh[1] it has been noted that administration of parathyroid hormone produces a rise in the content of calcium in the blood serum even after exclusion of external sources of the element through evisceration. In other words, since the hormone can exert its full action on the serum calcium even after complete removal of the alimentary canal, it is concluded that the action does not consist in controlling the rate of calcium absorption. Again, after the administration of parathyroid hormone, and while the serum calcium is high, there is no diminution in the excretion of calcium. The parathyroids, therefore, do not act by controlling the rate of excretion.

By a series of successive exclusions of important organs, Stewart and Percival have found that the liver, spleen, pancreas, pituitary, thyroid and central nervous system do not appear to have any special function in connection with the effect of parathyroid on the blood calcium. As increase in the serum calcium takes place under the influence of parathyroid hormone without any diminution in the excretion and without the possibility of any absorption from the alimentary canal, the seat of action must be shifted elsewhere. As the Scotch investigators conclude, the calcium drawn into the blood when parathyroid is administered must come from the soft tissues, from the bones or from both. They incline to the belief that the parathyroid hormone controls the distribution of calcium between the blood and the tissues by regulating the proportion of the total serum calcium that is readily diffusible. Such stress on the physicochemical condition of the elements in relation to their availability and "mobility" in the organism represents a decidedly modern tendency.

ACROMEGALY AND METABOLISM

The dominant rôle of the thyroid in the regulation of the basal metabolism, that is, the chemical changes or tissue combustions in the body that are independent of such influences as work and food, has become well established in recent years. Elaborate observations reported on several thousand persons with different diseases by Boothby and Sandiford[1] of the Mayo Foundation show that except in thyroid disorders and in leukemia there is little variation from normal of the basal metabolic level. A similar outcome is found in comparable studies at the Massachusetts General Hospital. For this reason the exact measurement of the basal metabolism has become significant in the diagnosis and management of thyroid disorder.

There have been suggestions that the suprarenals also have a calorigenic influence in the body through the liberation of epinephrine. Both epinephrine and thyroxin accelerate the heat production in the body. Precise explanation of the nature of the effect remains to be developed. The statistics for cases of Addison's disease, in which the suprarenals are defective, are too variable to afford a final answer regarding the actual rôle of the glands in normal heat production. With respect to a metabolic rôle of the pituitary in the energy exchange leading to heat production, the clinical evidence likewise has been confusing and conflicting. More convincing has been the experimental evidence secured from hypophysectomized animals which showed a marked lowering of basal metabolism in the state of hypopituitarism.[2] The possibility remains that any hormonal effects of the pituitary on heat production may be exercised indirectly through the thyroid.

[2] Benedict, F. G., and Homans, J.: The Metabolism of the Hypophysectomized Dog, J. M. Research **25**: 409, 1912.

An unusually significant contribution in this field has come from the Surgical Service of the Peter Bent Brigham Hospital in Boston. Cushing and Davidoff[3] have formulated the conclusion that acromegaly is a disease which bears the same relation to pituitary insufficiency (hypopituitarism) that exophthalmic goiter bears to myxedema (hypothyroidism). It is, in other words, an expression of hyperpituitarism just as exophthalmic goiter is of hyperthyroidism. Acromegaly is often accompanied by an elevated basal metabolic rate and the reverse condition of hypopituitarism by a subnormal rate. Acromegaly, furthermore, may be accompanied by a palpably enlarged thyroid and by symptoms suggesting thyreotoxicosis to which the increased basal metabolic rate has generally been ascribed. The Boston surgeons further conclude that the chromophilic cells of the anterior lobe of the pituitary body secrete a substance which not only contains the hormone of growth but which is capable of raising the basal metabolic rate. Whether the hypophysial principle under these circumstances acts as a stimulus to metabolism directly on the tissues or only through the intermediation of the thyroid cannot as yet be positively stated, they add, although there are reasons to believe that it may act independently. At any rate, the pituitary can no longer be entirely neglected in relation to metabolic upsets in the organism.

LAVOISIER AND THE SCIENCE OF METABOLISM

The present year represents the sesquicentennial of the real beginning of the science of metabolism. In 1777 the French chemist Lavoisier—on whom later the ax of the guillotine fell during the Reign of Terror—described the exchange of gases in respiration. This was the brilliant investigator who demonstrated that respiration in the body and combustion outside it are essentially analogous processes in representing an oxidative change with water and carbon dioxide as by-products. In a brief memoir published in 1777 he enunciated the principles that during respiration it was only "air eminently respirable" (oxygen) which disappeared from the atmosphere when an animal was put into a confined space, and that this air was supplanted by expired "aeriform calcic acid" (carbon dioxide); that when metals were calcined in air, oxygen was absorbed until its supply was exhausted; that after an animal had perished in a confined space and the carbon dioxide in the atmosphere was absorbed by alkali the "foul air" remaining was the same kind of air as that found after metals had been calcined in air in an enclosed space. All the former qualities of this air could be restored by adding to it "air eminently respirable."[4]

From these pioneer experiments it was thus seen at once that respiration is oxidation; that air which has been respired resembles air in which a metal has been calcined, so far that it has lost a certain quantity of its oxygen. But Lavoisier went further than this, Sir Michael Foster[5] adds; he saw that there is an essential difference between air in which a metal has been calcined and air which has been breathed. The latter contains what the former does not, Black's fixed air, for it precipitates lime water. Lavoisier, unlike Priestly, with no veil before his eyes, did not see reason to doubt that this fixed air came from the lungs; and he recognized accordingly that in respiration there are two factors, the disappearance of oxygen and the appearance of fixed air.

It has lately been asserted[6] that although the details of the forms of respiration apparatus used by Lavoisier and his collaborators Laplace and Sequin are unknown, it seems probable, as pointed out by Tigerstedt, that they made use of the two principles which have formed the basis on which have been developed all subsequent types of apparatus for the determination of the respiratory exchange. A busy world in which the science of nutrition has come to play a significant part toward the promotion of human welfare may well pause to pay a tribute of respect to the initiating spirit in its development. Lavoisier's untimely death is one of the unnecessary tragedies of history. Through his cruel execution, as Foster has masterfully expressed it, there passed away from this world, in his fifty-first year, this master mind of science, who had done so much to draw aside from truth the veil of man's ignorance and wrong thought, and there passed away too the hope of his drawing aside yet other folds of that veil, folds of which perhaps wrap us round even today.

THE PROTOPLASMIC REACTION OF LIVING CELLS

The student of physiologic functions can scarcely fail to be impressed by the nicety with which certain chemical reactions in the organism are conducted. Perhaps the most conspicuous instance of this is represented by the neutrality regulation whereby the blood maintains its remarkable fixity of reaction. According to Myers and Booher,[7] for example, the normal range of p_H for the blood probably lies between 7.35 and 7.43, values lower than 7.32 and higher than 7.47 being definitely abnormal. The maximum tolerated range is said to lie between p_H 7.0 and 7.8. To preserve this type of "normality" a variety of corrective or compensatory devices are at the disposal of the organism.

Resistance to changes in hydrogen ion concentration is brought about by buffer action. A buffer has been compared to "a sponge having the capacity of 'soaking up' hydrogen and hydroxyl ions." The buffers of the blood are salts of weak acids—the bicarbonates, phosphates and alkali salts of the proteins, including both hemoglobin and oxyhemoglobin. In addition to these safeguards there is the capacity of the body to excrete acid quite promptly through the kidneys, the volatile carbon dioxide being eliminated by the lungs. Furthermore, the organism seems to have base in latent forms ready to mobilize for meeting an acid emergency.

Whether the tissues themselves, and particularly the living cells, are equally capable of preserving their reaction unchanged within narrow limits has not been clear. It has long been known by students of biochemistry that when cellular tissues are crushed and examined by chemical methods an acid reaction speedily develops and may progress in intensity. Localized acidity of this sort has been regarded as a sign of tissue injury, likewise of circumscribed deficit of oxygen The consequences are sometimes apparent in localized abnormalities, as in the case of so-called Zenker's waxy degeneration of muscles. It can even be produced by excessive stimulation of the contractile tissue, whereby acid is formed faster than it can be removed.[8] A noteworthy contribution to our knowledge of intracellular reaction has been made by Chambers[9] and his co-workers at Cornell University Medical College Through their development of an elegant microsurgical technic it has become possible to inject into single cells indicator dyes that cannot penetrate them from without Chambers has observed that the protoplasm tolerates only a limited amount of the injected fluid If too much is injected the protoplasm undergoes visible disintegration, with the production of an acid which the dye immediately registers. As long as the cell remains alive, the final tint in the protoplasm is always the same

The new determinations of hydrogen ion concentration have already been made on the cells of ciliated epithelium, gastric and intestinal mucosa, liver, pancreas, striated muscle, and unripe ova. The p_H values obtained were the same for every cell: 7.5 ± 0.1 for the nucleus, both normal and injured; 6.9 ± 0.1 for the normal cytoplasm, and 5.3 ± 0.2 for the injured and cytolyzing cytoplasm. It is already apparent that the living protoplasm of widely differing types of cells under normal conditions apparently has a remarkably constant p_H value, which is slightly on the acid side, while the nuclear p_H is distinctly on the alkaline side of neutrality. Injury produces an increased acid reaction in the cytoplasm but does not affect the p_H of the nucleus. This affords a further striking illustration of the relatively unchanging environmental reaction in which the functions of living matter are carried out. It also enables one to appreciate better how and why seemingly insignificant uncompensated changes in the movement of acids and bases may lead to physiologic disaster.

DISGUSTING MEDICAL ADVERTISING

The medical profession is now being circularized with an illustration advertising presumably "Proveinase Midy." The circular shows a disproportionate naked Hercules, whose genitals are at least not inconspicuous, and a depressed naked female, in a somewhat September morn pose, whom the Hercules seems about to energize with "Proveinase." The name Midy has meant little that is inspiring to the American medical profession. Santal-Midy is merely sandal oil capsules that are no better than any others. Their exploitation is largely by way of posters in public toilets. What an insult to the medical profession that any firm should think that the picture referred to would appeal to its members! Such advertising merits only contempt and resentment.

IRRADIATED MILK

The newly discovered power of ultraviolet rays to confer antirachitic properties on various types of food is so astounding that the scientific world has scarcely recovered from the surprise and elation that followed the first announcements. The possibility, reported in a recent issue of The Journal,[1] of making a few milligrams of an isolated organic substance acquire, through exposure to suitable brief irradiation, an antirachitic potency equivalent to that of an entire quart of good cod liver oil fires the imagination and inspires an increased respect for the importance of "little things" in nutrition. Ultraviolet rays are, however, not to be regarded merely as a sort of plaything in the hands of untutored persons; nor should they become a tool for quacks. In a warning[2] against wholesale or hasty irradiation of foods it was pointed out that undue exposure to ultraviolet rays may actually produce deterioration in foods, so that great caution and expertness must be used in securing the desired beneficial results. Such warnings should not be allowed, however, to obscure or minimize the successful endeavors. In 1925, a group of investigators[3] at the University of Wisconsin demonstrated that, by exposure to the radiations of a quartz mercury vapor lamp, the antirachitic properties of cow's milk were increased eight or more times. Under the same conditions a sample of goat's milk increased in activity about twenty-four times. This increase in activity can also be induced rather promptly, *though to a lesser degree*, by direct irradiation of the animal. Supplee and Dow[4] have recently demonstrated a comparable effect on dried milk, to which irradiation imparts measurably greater *antirachitic and calcifying properties; and this is true* not only for winter-produced milk, which is usually comparatively poor in antirachitic potency, but also for milk produced under the better natural conditions that prevail in summer. The potential capacity of milk for calcifying properties is not fully attained under the natural conditions of production. Apparently the utilizable increment of antirachitic potency imparted to winter-produced milk by irradiation is greater than the utilizable increment imparted to the summer product. The results of Supplee and Dow appear thus to confirm the existence of a significant interdependence between antirachitic properties and the degree of ultraviolet radiation to which the product itself, or its synthesizing agent, the body of the cow, has been exposed. These advantages of irradiation can be secured, under proper conditions of treatment involving only a brief exposure to ultraviolet rays, without impairment of the other nutritive properties of the milk.

THE SOCIETY FOR EXPERIMENTAL BIOLOGY AND MEDICINE

Nearly a quarter of a century ago, on January 19, 1903, a small group of scientific investigators in New York met at the call of Professor Graham Lusk and the late Dr. S. J. Meltzer to consider the organization of active workers in experimental biology and medicine. This was the meeting that initiated the Society for Experimental Biology and Medicine under the presidency of Dr. Meltzer. The main object of the organization was the cultivation of the experimental method of investigation in the sciences of experimental biology and medicine. Membership in the group was limited to persons who had completed some meritorious independent experimental research in that field of study. The programs, from the start, consisted in brief presentations of the essential features of experimental investigations, and frequently of demonstrations of actual experiments. The membership soon outgrew its confinement to "Greater New York" and spread throughout the country. One reason for the success that has attended the development of this society lies perhaps in the significant circumstance that it has aimed to bring together workers in many fields, such as physiology, biochemistry, biology, bacteriology, pharmacology and experimental medicine, at a time when rapidly developing specialization had already begun to segregate investigators into small groups. The new society thus represented a wholesome reintegrating force and provided a stimulus for the discussion of "borderline" and interrelated problems. It has become an influence tending to overcome the danger of narrowness in the present-day outlook on the natural sciences with which medicine is so closely bound up. Another early object of the society was the development of high standards of presentation and scientific criticism. Incidentally, not a few significant discoveries have been announced for the first time at its meetings. As might be expected, this movement was bound to be followed by similar endeavors elsewhere. Many of them have resulted in the organization of branches of the society. Today ten branches are located all the way from New York to Peking; eight more are at present under contemplation. The contributions, in the form of brief, concise summaries, are embodied in the *Proceedings of the Society for Experimental Biology and Medicine,* which is available through subscription. This journal deserves the active support of members of the medical profession, who are likely to find it stimulating and informative. Published without special endowment and maintained by the contributions of scientific workers, it needs and enlists the help of those who can benefit by its program.[1]

CONFERENCE ON PUBLIC HEALTH

Held in Chicago, March 24-25, 1927

Dr. Wendell C. Phillips, New York, President of the American Medical Association, in the Chair

March 24—Morning

Preventive Medicine and Health Education

Dr. Wendell C. Phillips, New York: Two basic ideas must necessarily prevail in any properly conducted health conference; i. e., preventive medicine and health education of the public. The *why* of these problems needs neither discussion nor confirmation in this presence. We are not here to discuss the *why*, but it is within our province on this occasion to give wholesome consideration to the HOW of the problems. I modestly venture to suggest two keynote ideas which may well serve to guide our meditations, our deliberations and our discussions. The first is mutual and, hence, *better understanding*. The second is *team work.*

I would stress the important position which the American physician has gained not only as the personal and family councilor but as adviser in health and sanitation affairs. He necessarily is by tradition, education and experience qualified for this service. It seems unwise to inaugurate a health program in any community without first securing not only the support but also the active leadership of the local profession. The lack of such understanding and mutual effort has in numerous instances resulted in harm to the cause. We must admit that the education of the physician up to the present time has stressed disease and its treatment, rather than health and its preservation; nevertheless, the physician remains the only individual in the community with adequate basic knowledge available for service in health matters. We freely admit that changes in the curriculum in undergraduate medical schools are necessary. The student of medicine must be trained to treat the individual from the standpoint of health as well as that of disease. Such changes in medical education, of course, contemplate instruction in personal and community health education. We affirm a deep seated conviction that the family physician should remain the foundation of medical service. Our activities in preventive medicine and health education should be guided by principles and programs which will prevent duplication.

It is my sincere conviction that the medical profession should throw off its mask of reticence and its shrinking attitude toward reasonable publicity concerning health education. The House of Delegates of the American Medical Association is on record as favoring every proper method of public health education, including periodic medical examinations of the supposedly healthy. Our journal, *Hygeia*, published distinctly for the lay public, exemplifies the attitude of organized medicine toward this project. Clip-sheets from every issue of *Hygeia* are furnished to hundreds of newspapers. Furthermore, many of our great newspaper syndicates, great daily newspapers and reputable magazines refuse to publish any material pertaining to health except on reliable medical approval. Indeed, in health matters, many of these publications rely constantly on the advice received from the American Medical Association headquarters. Our future progress is not likely to be lacking in human effort and instrumentalities, but it will depend on the large amounts of money that may become available for its promotion. Millions and then more and more millions are needed. A higher average of overflowing good health means a higher average of happiness, comfort, usefulness and the economic value of the individual.

The Relations of the Physician to Public Health

Dr. Hugh S. Cumming, Surgeon General, U. S. Public Health Service, Washington, D. C.

Dr. Harlow Brooks, New York.

Dr. Arthur T. Holbrook, Milwaukee.

These three papers appear in full in this issue of The Journal.

Dr. Frank W. Cregor, Indianapolis: The medical profession is the one body which has dedicated its life to a study of the science and devoted it to the practice of the art of healing. Medical practice presupposes individual service. While this is true, it yet remains that it is the one body qualified for public health work. Its ideals and traditions, its culture and the character of its citizenship compare favorably with that of any branch of society.

The medical profession through its organization is the one thing to which the state should look for aid and guidance in all its health activities and the physician who is employed as a health officer or as a commissioner for the state or officer for the county, city or municipality should receive the endorsement of the medical profession and the state should first demand this endorsement. The activities of its health officers should at all times reflect the composite view of the medical profession.

The health department of the state and the medical profession through its organization should make an earnest mutual effort to come to a common understanding. The medical profession needs this as a means of discharging its public obligation. The health department needs it if it is to keep its professional point of view clear and accomplish its great purpose. An annual conference between the health department and some authorized body representing the medical organization would be helpful. The results of this would be reflected down through their separate organizations to the county units. A health officer should be as anxious for the support of his local medical society as for the approval of the health department. The health department simply represents a means of applying the knowledge of the medical profession for the public good. Perhaps the medical profession, which can speak collectively only through its organization, has been timid and hesitated to thrust its views on the state, feeling that the state should come to it. Possibly the state, because of its limited knowledge of the medical organization, has not thought of approaching it. I encounter physicians who decry any activities on the part of the medical organization which might be construed in any way as political. I have also observed that they are the ones who criticize most and wail loudest about existing conditions. I believe that proper activities along these lines are the very best evidence of good citizenship. To my mind, if the relations of the physicians to public health can be worked out along these lines where the activities of the health department can represent the composite views of the medical profession in matters pertaining to the public health, it will be safe, sane, efficient and satisfactory.

President Phillips: The discussion of these papers should be most interesting, and the opportunity will be given at the opening of the session this afternoon.

March 24—Afternoon

DISCUSSION ON PAPERS OF DRS. CUMMING, BROOKS, HOLBROOK AND CREGOR

Dr. George M. Fisher, President, Medical Society of the State of New York, Utica: We in New York State, like all other states in the Union, have had more or less trouble with our lay organizations. That led me to think that perhaps there was some ground on which the medical profession and the lay organizations could get together. The result was that I talked it over with the State Charities Aid and the Milbank Foundation and they extended to the medical profession a most hearty greeting, and agreed that they would form a committee and meet with a similar committee from the state society. Now the proposed discussion brought before that committee was, first, in all communities there exists a large amount of illness and poor health which does not seek and, therefore, does not receive medical diagnosis and treatment, at least not at a favorable stage. Second, important new discoveries and improvement in preventive medicine should be made available at the earliest practical time to all persons seeking medical aid. Third, sound public policies demand that all persons, irrespective of residence, should have available the essentials of reasonably good medical diagnosis and care when ill. Fourth, the continued economic security and well being of the medical profession is an essential factor in meeting the preceding condition. Fifth, in all health clinics and activities, the service of local physicians should be utilized and remunerated except where special skill or service is required. Sixth, no responsible person seriously proposes or has proposed the introduction of an actual system of state medicine in the state of New York. Seventh, in order to conserve the largest usefulness and economic well being of the medical profession, and at the same time to bring progressive measures for the protection of health to the population generally, and to the interests of the population, to the medical aid, both curative and preventive, it is highly important that definite understanding should be reached between those whose primary interest is the practice of curative medicine, and those whose primary interest is the promotion of preventive health activity. As a tentative base of such an understanding the following are suggested for discussion: the tuberculosis program, which met with a very liberal discussion, and then the mental hygiene program, the prenatal care, child health program, social hygiene program, and lastly communicable diseases. In all these discussions the physician was foremost in place. The work of this committee has so far been so successful that it is my intention to propose to the state medical society that a permanent committee be appointed to be known as the Public Relations Committee, the object of which is to deal with public organizations, lay organizations and societies as well as the health authorities of the state. Furthermore, I propose that in each county society there should be organized also a public health committee whose relations shall be in connection with that of the state society and work along the same line.

Mr. Homer Folks, State Charities Association, New York: No lay organization, so called, concerning itself with health or even with the relief of distress and poverty, which is what they all began with, is composed of laymen alone, to the best of my knowledge. They all have physicians in their membership, on their boards, on their executive committees. We don't particularly object to the term "lay organization" except that we like it borne in mind always that no lay organization, that I know anything about, ever does anything in the scientific line, ever adopts a policy, ever takes any action of any sort or description that borders on a technical character, without the most minute and authoritative direction from its medical people. As to the particular organization to which Dr. Fisher refers, the State Tuberculosis and Health Committee of the State Charities Aid Association, we have concerned ourselves since 1907 with the prevention of tuberculosis in the state of New York, outside New York City. We also have a state mental hygiene committee, active in the state as a whole. We have distinguished psychiatrists and distinguished sanitarians on that committee. We are proud of the fact that though we have published millions and millions of circulars, leaflets and publications dealing in a popular way with scientific facts, we have never been called on to retract or modify during that thirty-year time any statement we have made because of any technical or scientific inaccuracy. I mention that merely to show the standing and ability of the medical men who have guided us, and of the extent to which we have been glad to be guided by them. I became firmly convinced a couple of years ago that most of the difficulties between the medical practitioners and health organizations, public or private, arose because they all approached the subject, as Dr. Brooks unfortunately did, from a rather general point of view A year ago we had the pleasure of meeting informally several times with several members of the state society to see if we didn't agree, as Dr. Fisher mentioned, on the details of the tuberculosis clinics, what patients should come to them, and so on Somewhat to the surprise of some of us, we found we didn't differ at all about the actual, practical, concrete content and the desirable modes of operation of those activities, so that we were delighted to receive Dr Fisher's informal suggestion last fall of such a conference committee meeting now officially and in a representative capacity We have found no real difficulty at all in covering the field, so far as we know it, and in arriving at entirely unanimous recommendations to be made by Dr Fisher's committee to the state society, by our committee to the state-wide health group

Dr John A Kingsbury, Milbank Memorial Fund, New York There are probably just as many varieties of social workers as there are of doctors I think that the President of the American Medical Association and the president of the New York State Medical Society have marked the beginning of a new epoch by arranging for conferences where physicians and public health workers get their feet under the same table, and begin to understand one another I yield to nobody in my admiration of Dr Brooks as a physician, but not as a judge of social workers I want to record a little bit of history I talked about a little Cattaraugus County difficulty with Dr Phillips when I had the pleasure of lunching with him one day in New York I said, "We must find a way to promote better understanding between doctors and public health workers," and it was only a day or two after that he called me on the telephone and said, "Dr Fisher is in my office" Dr Fisher came to the telephone and made a suggestion, which he said he and Dr Phillips had been talking over I transmitted that information to Mr Folks Out of that incident grew the Public Relations Committee of the New York State Medical Society, which has been meeting with a similar committee of the New York State Charities Aid Association selected by Mr Folks I think that ought to be on the record, because it may usher in a new epoch in medical and public health relationships

Twenty years ago I started organizing the voluntary committees on tuberculosis prevention in New York State I went out with my instructions from the chief who just preceded me The first thing at the head of the list of instructions was "Go and see the president of the county medical society, consult with the county medical society" We never failed to do it The first thing we did in Cattaraugus County was to consult with the county medical society There are about sixty-eight members scattered over 1,300 square miles of the county; some bad roads, very bad roads, doctors busy, very busy; and eight or ten is a large attendance at one of those meetings We came out all right with those ten, we got started harmoniously The president of the society came to the general meeting at which the plans were approved Two members of the county medical society were put on the county board of health, and all seemed well, but it wasn't quite well So, about three years later, there was a little blow-up at a meeting at which about twenty one members came together Later when they assembled a still larger meeting, after getting together as Dr Fisher has suggested, after smaller group meetings, promoting an understanding of what was doing, the county medical society at this larger meeting passed a resolution endorsing the county health unit, and the general program that was being carried on with the aid of the Milbank Foundation but carried on by the local agencies, under the supervision of the State Charities Aid Association We have gotten together and apparently all is well, but all will be well there as time goes on only if we succeed in understanding one another

Dr Henry F Vaughan, American Public Health Association, Detroit Mr Kingsbury spoke of the situation in Cattaraugus County where there were brought together representatives of the medical society Of some sixty eight members of the society only eight came, and those eight who came fully comprehended and understood the situation and were willing to cooperate The sixty who didn't come, didn t understand, were ignorant of the situation, and instead of cooperating they were antagonistic until they could be reached The same thing is true in every part of our country. When we meet with representatives of the medical society we soon have their confidence They see that we are able to get around the same table and put our feet under the same board and understand one another, but it is very hard to reach those sixty other physicians who do not come to such meetings It seems to me that the American Medical Association has a wonderful opportunity to reach those sixty men, and that if you are going to do anything constructive there ought to be some central bureau or authority in the American Medical Association which can interest those sixty men in local public health work I feel it in my own community, and I am sure every other health worker does We can reach them, but it requires continual prodding and propaganda work on our part It needlessly takes a lot of our energy, and it is a waste of time, because we get such trifling results If the American Medical Association could have through its Council on Health and Public Instruction or through some other agency a well defined method of reaching these other physicians in exactly the same way they are reaching the public through *Hygeia* and through propaganda work, we could get the sixty men back of the public health problem It seems to me that it would be a great mistake for this gathering to adjourn without working out at least some tentative program whereby the representatives of the various lay, nonofficial and official agencies and, above all, the private practitioner in medicine can have a common meeting ground, and that common meeting ground should start at the very top The relationship between the American Medical Association, the American Public Health Association and the official social agencies at the present time is virtually nil There should be a common understanding from the top right down to the bottom, with some line of organization, so that we feel the impulse and the effect of such a cooperative movement way down to the smallest unit

Dr C A Harper, State Health Officer, Madison Wis As was just stated, public health officials fully realize that the cooperation of the medical profession in the main is essential to successful aggressive public health work I desire to emphasize the necessity of the medical schools adding a stronger and more basic branch of the essentials of public health as a part of their regular curriculum It has been shown in this discussion that the divergencies between public health officials, small as they are, and the medical profession is more through misunderstanding than it is in actual opposition

Dr W S Leathers, Professor of Preventive Medicine, Vanderbilt University School of Medicine, Nashville, Tenn I did not get just the reaction from the paper of Dr Brooks that has been expressed by the speakers who have discussed it It seemed to me that the question was discussed by him from a broad point of view as related to the practitioner of medicine and I do not think that he meant to imply that there were not capable social workers just as there would be efficient workers in every legitimate field of endeavor It appears to me that this paper, in the main, was stimulating and constructive In the state in which I served as state health officer for fourteen years, I made it a principle of administrative procedure not to undertake health work faster than I could obtain the intelligent cooperation of the medical profession It seems to me that this is fundamental When I left the state (if you will pardon me for the personal reference), I believe as many as 95 per cent of the physicians were supporting the state health work I have found practitioners of medicine my best friends An effort was always made to confer with them concerning community health problems and secure their support When differences occur between the profession and public health workers it is usually the result of misunderstanding This conference is a forward movement for bringing about better conditions between official and nonofficial agencies in relation to the practitioner of medicine

Dr S J Crumbine, American Child Health Association, New York Dr Holbrook of Milwaukee expressed my sentiments I am in accord with one single exception, that is the recommendation that only local men should be chosen for health officers. Frequently that is impossible, it is extremely difficult many times, and I think often insures the failure of a program of public health.

Mr. James L. Fieser, American National Red Cross, Washington, D. C.: The experience of the organization which I represent has been an increasingly wholesome one in so far as its relationship to the medical profession is concerned. In the first place, the Red Cross through its 3,500 or so local branches has doubtless enlisted the service of many thousand physicians, just as in its work in special health fields, such as first aid, many thousand physicians have been constantly engaged in instructional work of a public health sort. Incidentally an examination of our instruction and literature will indicate an urge oft repeated that the local medical societies be taken into account. We have found by experience in time of disaster, for example, that after the first emergency has normally been taken care of by physicians in the community and those who came in, such affiliation is invaluable. In the field of general health activities, such as home hygiene and care of the sick, every effort is made to make clear that the instruction given is merely an aid and not a substitute for the more thoroughgoing work which only a physician can give. In other words, it is designed to give to the physician in the aggregate throughout the United State, an intelligent lay support when he goes into the home of that one individual representing 500,000 women who have satisfactorily completed such a course today. Within ten years, through local and Red Cross societies, one out of every three counties in the United States has inaugurated a public health nursing program, which again ties in definitely with an instruction that the nurse in nowise is to be a practicing person but in every instance is to follow the instructions of a physician. Of course, in the case of the Red Cross, we have almost a threefold entity: first, a governmental one through which we have the counsel constantly of the surgeon generals, two of whom are represented on our central committee of eighteen. In the second place we are a popular agency, and are therefore constantly urged to do things that we cannot do in the health field and do not want to do. In the third place, we have a professional relationship both to the social work group and to the medical professional group in which connection we constantly strive to have the counsel of the best available people in both fields.

Dr. B. Franklin Royer, Medical Director, National Commission for Prevention of Blindness, New York: I think a little of the trouble existing at times between the medical profession and some of the lay organizations develops because physicians have been so busy preparing themselves for the job of curative medicine that they have failed to keep up with the trend of modern prevention. As medical men they have undertaken to teach the public with altogether too little health knowledge. I think that has resulted in misunderstanding. I am sure that meetings such as this will enable both sides to get a better point of view, and if it does nothing more than to make the medical profession see its own weaknesses and its own backwardness at times in engaging in the real field of health promotion, it will have done a great deal.

Dr. Clifford G. Grulee, American Child Health Association, Chicago: It seems to me that most of our difficulties have been difficulties of misunderstanding, but there have been some difficulties that have been real. One of the difficulties that has been real has been the failure to distinguish between curative medicine and preventive medicine. The people at large, the laity, feel that they should have public health work free. The physician feels that they should not have curative work free, and unless we can distinguish between the two there will always be that disagreement between the medical profession and the laity. That is one of the practical questions that we must settle.

Dr. Herman N. Bundesen, Health Commissioner, Chicago: It has been well said that a wood shaving has two sides; it couldn't be a shaving if it did not have two sides. I think that the way to look at many of the problems of the health official. There isn't any doubt that the solution of a problem depends largely on the personal equation of the men who happen to be in charge of organizations that may be having misunderstandings with one another. In Chicago, when I became health commissioner, Dr. Ferguson, president of the Chicago Medical Society, came into the office and pointed out to me what appeared to be several justifiable complaints. They were corrected, and we have had fine cooperation with the Chicago Medical Society and magnificent cooperation with the American Medical Association. We feel that in the Chicago Department of Health problems can be solved if both parties will take a reasonable attitude and agree that there are two sides to every story.

Dr. W. F. King, Secretary, Indiana State Board of Health, Indianapolis: Indiana has as much cooperation between the organized medical profession and the official health departments as can be found anywhere. One of our great difficulties, however, is to be found in the fact that many physicians are not members of the county and state societies. There are 4,100 physicians in Indiana, of whom less than 2,800 are members of the state medical association. We find it difficult to get the cooperation of the physicians of a community, either through the medical society or outside the medical society because of this situation. If we can have an inclusive medical profession with all physicians as members of the organization, it should be possible for the medical profession to extend its circle of influence to take in the public health officer or public health administrator and those who are responsible for the direction of nonofficial health organizations, and that all can then work together with full understanding and confidence. I hope that the fine spirit of this meeting can be carried down to the local medical society and through the society to the local community.

Dr. D. B. Armstrong, Metropolitan Life Insurance Company, New York: I hope that before we get through we may have some opportunity to take up the relation of the individual physician to public health, and especially personal hygiene. This involves, of course, the transmission of information to people about how to live, and that is partly a job of the practicing physician. It should enable the average citizen to know the difference between the qualified practitioner of medicine and the chiropractor. It should help the average newspaper reader to know the difference between an editorial or article on smallpox sent out by Dr. Greenburg's organization, that is the American Association for Medical Progress, and an article or editorial on the same subject in McFadden's *Daily Graphic*. Then, of course, there is the question of getting the physician willing and able to meet the demands that a better informed public is going to make on him. There are still a good many physicians not yet willing and able to practice preventive medicine. For instance, we have hundreds of letters every month in the office with which I am associated asking about health examinations. The writers state that they have been advised to go to the doctor for a health examination. They complain that the doctor examined only part of them, or didn't do the job thoroughly, or gave them little really helpful advice about the hygiene of daily living. To a greater and greater extent the private citizen is being taught to seek health advice from the doctor. What agencies should guide him and by what means? He is trying to find the doctor in this field. Will he find him wanting?

Dr. William Allen Pusey, Chicago: Nobody can enjoy his prejudice after he gets on intimate terms with a man against whom it is directed. There is undoubtedly some room for better understanding between our profession and what we, with no intention of superiority, call the lay groups. I have had occasion to deal very frequently with lay organizations that have to do with health and I am ready to testify that, with rare exceptions, these experiences have been exceedingly pleasant. The workers are enlightened, intelligent. They are quite as well informed on their side of these problems as we are on ours, and they are very helpful. But it must be faced that sometimes this story is not so pleasant. I recall that at the present time Chicago medicine is suffering a grievous wrong in what, in my opinion, is an unwise adventure of a lay group in medical matters. This is partly due to the medical profession because we did not get before them, in the way that we should, all of the factors of the situation. These occasions do occur and it is highly desirable that the profession and organizations engaged in medical and physical welfare work should try to see things from each other's standpoints and guide their courses in the light of expert information on all sides.

There was one expression that was occasionally used this morning that I often hear and which I think carries a bad impression to the man who doesn't understand; that, is the reference to the "rights" of the medical profession. Of course the medical profession has no rights at all in the sick; sick people are not made for our benefit. We are an expensive necessity, maintained for them. But in one sense medical men are entitled to certain privileges that are important to cultivate and they rest on the fact that, competent or incompetent, the medical profession represents all that society has for the treatment of the sick and injured. If a foundation or health organization goes into a community to help in health *work or in the treatment of the sick, as it sometimes* does, and pursues a course that is fundamentally opposed to the welfare of the medical profession, it is a socially bad act, an act that is bad not primarily because it is bad for the profession but because, being bad for the profession, it is bad for the community. For it is to the interest of the community to have the best physicians it can get, and if in a proper sense the physicians' interests are not protected the community cannot expect to have the best physicians that are available. It is necessary that medical men live; they will likely be on the ground after the organization goes away, and the organization is dependent on them for its detail work. With all our altruism most of us have families and we have to eat, and until we become endowed or taken over by the state—both of which contingencies, God forbid—we shall have to make a living.

Dr. Rachelle S. Yarros, Associate Professor of Social Hygiene, University of Illinois College of Medicine, Chicago: I have lived in Chicago and practiced medicine for thirty years. I have worked with almost every agency that has begun to do health work, and I think the people of Chicago, the enlightened people of Chicago, are always ready to be guided by the physicians. But, as Dr. William Allen Pusey said, some of the leading men and women in the profession have been too busy doing good medicine. Consequently, they have not taught the lay public as much as they should have. The public is ready for education in social hygiene and venereal disease. Right in the city of Chicago there is less cooperation with the social hygiene work of the lay group than in any other direction, and we appeal to the physicians not to isolate themselves into a separate clique. The public needs them, and they need the public.

Prof. Ira V. Hiscock, John Hancock Mutual Life Insurance Company, New Haven, Conn.: There is just one aspect of this problem which may seem somewhat afield from the discussions so far, although it has been mentioned by Dr. Harper, and also by the President in his talk this morning. The point I should like to make relates to medical education, because the relation of the physician to this public health movement in the future will undoubtedly be influenced a great deal by the type of education that is given in the medical schools. One thing which has impressed me very much is the possibility, referred to in the publications of the American Medical Association and in other places, of starting the public health education of the men who are going to be the practicing physicians in the very early years of their course in the medical school. If these men are given a glimpse of what preventive medicine means in the early years of their course, in pediatrics, in pathology and in medicine, when they come to the courses in the principles of public health they are going to have an entirely different attitude than they would have otherwise. Furthermore, they are going to have a different attitude toward the problem as a whole out in the community. We have found that it means a great deal to the students in the principles of public health course in the medical school, if they do get an insight into the whole problem through the other courses which are not exactly labeled public health.

Mr. Homer Folks, State Charities Association, New York: I want to get on the record another important phase of cooperation between the state medical society and the lay health organization of New York State. Six years ago a chiropractic bill passed the legislature and got up to the governor, and there was an imminent probability it would become a law. At the suggestion of the state medical society and the state health department, the lay organization organized the lay forces of the state to defeat the bill, and the counties of the state were practically all represented in a hearing before the governor and were working actively against the bill. Through this union of effort the bill was vetoed. Since then, for six years, they have been held absolutely a unit in opposition to chiropractic and all similar legislation. Last year an important medical practice act was introduced, framed by the state medical society. They said they would like us to help; we were delighted to do it. We organized every county in the state. There was a big educational movement among the lay people as to what a medical practice act should be, and for the first time in more than a decade a really good medical practice act became a law in New York State.

Dr. Harlow Brooks, New York: I want to point out what seems to be the great lesson of the talk this afternoon. Where people get together to talk these things over face to face, as Commissioner Kingsbury and members of our medical board did a few years ago, a mutual respect and a cooperative understanding is sure to come forth. I think it is well to know where we stand and to know the reactions of the profession to lay activities in public health matters. I think I have tried to portray this in a rather definite and thoroughly frank way with some result, apparently. The thing to do is to get together.

(To be continued)

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Institute on Public Health.—The first annual institute on public health, under the auspices of the Los Angeles County Public Health Association and the advisory board of the county health department, opened, June 20, at Los Angeles, and will end, July 9. It was made possible through the financial assistance of four members of the staff of the county health department and the county public health association with the hope that the standard of local health activities will be raised. The principal speaker was Charles-Edward A. Winslow, Dr.P.H., Anna M. R. Lauder professor of public health, Yale University School of Medicine, New Haven. Instruction was arranged under two heads: (1) a technical course given during the morning hours for physicians and other health workers, and (2) a popular course of six lectures in the evening given in the auditorium at Patriotic Hall, 1816 South Figueroa Street.

CONNECTICUT

State Medical Election.—At the annual meeting of the Connecticut State Medical Society, Hartford, May 25-26, Dr. Daniel Sullivan, New London, was elected president; Drs. Frank W. Stevens, Bridgeport, and Warren Avery Tanner, Danielson, vice presidents; Dr. Charles W. Comfort, Jr., New Haven, secretary, and Dr. Phineas H. Ingalls, Hartford, treasurer. The next meeting will be held, May 23-24, 1923, at Bridgeport.

Appointments at Yale.—The appointment of Dr. Grover F. Powers as professor of pediatrics at Yale University School of Medicine was announced, June 16. Dr. Powers is a graduate of Purdue University and Johns Hopkins University School of Medicine, where he was an instructor and associate in clinical pediatrics, and physician-in-charge of the pediatrics dispensary from 1916 to 1921. He then joined the faculty of Yale University School of Medicine as assistant professor o pediatrics. The following instructors have been appointed a Yale: Dr. Thomas Francis, Jr., medicine; Dr. Francis B Carter, obstetrics and gynecology; Dr. Sigurd C. Sandzen surgery, and Dr. Robert Salinger, pediatrics.

Diploma Mill Echoes—Koutsompous and Professor Scotellaro.—Testimony at rehearings in Hartford of the eleven eclectic physicians whose licenses had been revoked, noted in The Journal, June 25, indicated that all the honorary degrees issued by the Kansas City College of Physicians and Surgeons had been paid for except one issued to William Koutsompous of St. Louis, whose Connecticut license was revoked in 1924 on request of the Connecticut Eclectic Medical Examining Board. Ralph L. White, New Canaan, a member of the former Connecticut Eclectic Examining Board, is said to have testified that he was given a diploma from this school but that he destroyed it because he did nothing for the school either in service or money. James E. Hair, secretary of the eclectic examining board, testified that he also received a diploma during a casual Sunday stopover in Kansas City. Frederick A. Waite, Ph.D., Cleveland, Ohio, formerly special investigator for the Missouri state board, testified that Waldo Briggs, dean, St. Louis College of Physicians and Surgeons, appointed Nicholas Scotellaro a professor in the physiology department, and considered him qualified to teach, although it appears that Scotellaro failed in his premedical examinations at Fordham University, and also in the first year examinations at the College of Physicians and Surgeons of Baltimore, passing these on reexamination and passing the second year examination on a retrial; he failed twice in the third year examinations and was dismissed, going then to the St. Louis College of Physicians and Surgeons where Dean Briggs examined and passed him with all conditions removed; he graduated there in June. Robert Adcox, who was sentenced to prison as a result of his connections with diploma mills but never served, and Harry T. Brundidge, reporter for the St. Louis *Star*, whose investigation for that paper led in large part to the investigations carried on by state authorities in Connecticut and Missouri, were among the other witnesses for the state. Much of their information was published in The Journal at the time of the diploma mill investigation.

GEORGIA

Dr. Hardman Inaugurated as Governor.—Dr. Lamartine G. Hardman of Commerce was inaugurated, June 25, as the fifty-sixth governor of Georgia Dr. Hardman practiced medicine in the state for many years, retiring about 1919 to engage in the business and industrial life of his community and the state. He is the first physician to become governor of Georgia (The Journal, Oct. 23, 1926).

Renovation of Medical Building.—The departments of the University of Georgia Medical Department, Augusta, that were affected by the recent school fire are being renovated; the roof, the only part that burned, is being restored. The damage was estimated at $16,000. Space in the south wing, heretofore unused, is being converted into quarters for the department of experimental surgery with a large operating room, three rooms for research and an office. The space formerly used by the surgical department on the first floor will be taken taken over by the department of public health. The medical department is appealing to the legislature now in session for an increased appropriation of $20,000 a year for maintenance to replace a similar amount that has been received for the last five years from the Carnegie and Rockefeller foundations, which contract has expired. The public spirited citizens of the community and "official Augusta" contributed a similar amount to that given by the foundations, and these funds were used chiefly to inaugurate full-time departments in medicine, surgery and obstetrics.

Students Establish Loan Fund from "Breakage Fees."—The class of 1927 of the Medical Department of the University of Georgia has established a loan fund for needy students by turning back to the school the unused portion of money deposited as "breakage fees." The fund will be added to yearly until fifteen graduating classes have contributed to the fund, when the student council or faculty committee may apply further deposits to the advancement and expansion of the medical department. Former graduates shall be given the privilege of contributing to the fund as well as other persons. Loans shall be limited to needy students recommended by the student council and by a committee of two members from each class and approved by a faculty committee. The attitude, moral character and financial status shall determine the eligibility of students desiring loans. The precedent for establishing this fund was set by Dr. James R. Howell of the class of 1926, who, in conjunction with all the members of the class of 1927, signed a fitting set of resolutions to the students of the medical department of the university.

ILLINOIS

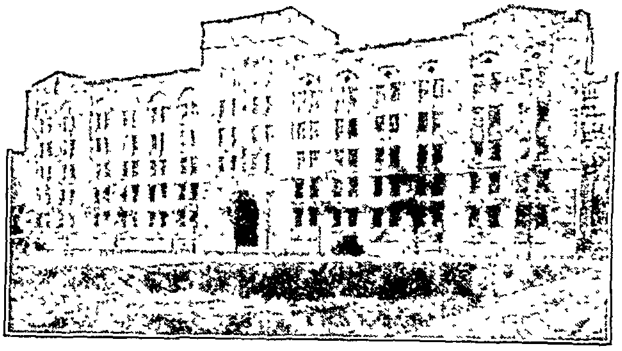
Society News.—Dr. Dana B. Seger, Morrison, was guest of honor at a dinner at the Morrison Country Club, June 16, given by the Whiteside County Medical Society in celebration of his fiftieth year in the practice of medicine. The president, Dr. Charles E. Parker, spoke on "Early History and Practitioners of Whiteside County," among other speakers was Dr. John E. Tuite, Rockford, president-elect of the state medical society.——Dr. Maurice L. Blatt, associate professor of pediatrics, University of Illinois College of Medicine, Chicago, addressed the Rock Island County Medical Society, Moline, June 14, on "Infant Feeding."

Chicago

Chiropractor Breaks Patient's Back.—George E. Ingram, an unlicensed chiropractor, was arraigned in municipal court, June 21, to answer, it is reported, his own charge of breaking the back of a patient under treatment. Ingram is said to have gone to the office of the state board of registration and education and reported that he had injured the patient. He was granted a jury trial, and as he was unable to furnish bond was placed in jail. Ingram came to Chicago recently from Oklahoma.

Society News.—Dr. Charles Davison, emeritus professor of surgery, University of Illinois College of Medicine, Chicago, gave the commencement address at the University of South Dakota, Vermilion, June 6, on "Prevention of Disease."——At the annual election of officers of the Chicago Medical Society, June 13, Dr. Frank R. Morton was elected president-elect and Dr. James H. Hutton, secretary. The president of the society for the ensuing year is Dr. Isaac A. Abt.——A request from the Chicago Field Health Officers' Association to have the affiliation with the Chicago Medical Society changed to the present name of the organization, Chicago District Diagnosticians' Association, was disapproved at the June 14 meeting of the council of the Chicago Medical Society.

Progress in Physiology Department.—Since the establishment of the physiology department of the University of Chicago, 108 students have been granted masters' degree in physiology, in most cases only after the completion of a piece of research constituting actual contribution to knowledge and published in a scientific journal. Fifty-five students have been granted the degree of doctor of philosophy (thirteen under the chairmanship of Professor Loeb, two under the chairmanship of Professor Stewart, and forty under the chairmanship of Professor Carlson); of these fifty-five doctors of philosophy, five are in the practice of medicine, four are professors of medicine; two professors of pharmacology, one a profesor of biology, one a professor of milk production and one an instructor in English; several are professors and instructors in physiology in twenty-eight universities in the United States and Canada; one is in charge of a missionary hospital at Korea, one is in the Peking Union Medical College, China, and four are dead. Eleven of the graduates of this department are at present in the University of Chicago; one in the department of pharmacology, one in the department of surgery, four in the department of medicine and five in the department of physiology. A total of 607 papers and seven books had been published from the department up to June 30, 1926. The department, now established in the new building represented here north of the Albert Billings Memorial Hospital, was open to the public, June 11, at which time scientific demonstrations were given by the staff.

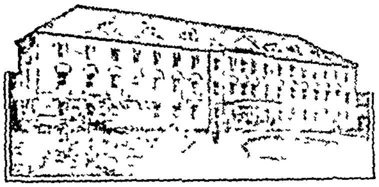


INDIANA

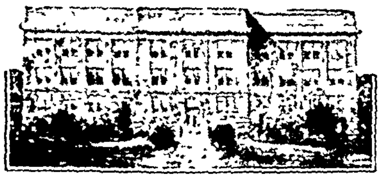
Personal.—Dr. Elmo Ray Royer has been appointed medical director of Milan Springs Hotel, Milan; Dr. Royer was formerly assistant director of the new Highland Sanatorium in Martinsville.

Dr. King Reelected.—At a meeting of the state board of health, June 14, Indianapolis, Dr. William F. King was reelected secretary of the board; Dr. James A. Turner, Ladoga, was elected president of the board at this meeting, and Dr. Amos J. Hostetler, Lagrange, vice president.

New Buildings at State Medical School.—Three new units are under construction or planned for the Indiana University School of Medicine, Indianapolis. The William H. Coleman Hospital for Women will be opened in October for patients from all parts of the state either as charitable, part-pay or pay patients. The hospital, donated by Mr. and Mrs. William H. Coleman in memory of their daughter, will cost $350,000 and accommodate seventy-five patients mostly in private rooms. It is red brick and Bedford stone and almost entirely fire-proof with soundproof walls. A state appropriation of $75,000 a year will be available for maintenance. The medical school unit under construction was started in 1917 but not finished on account of the World War. Funds to complete the structure have been provided by the sale of the old medical school building at Market Street and Senate Avenue to the state for $100,000. The legislature has appropriated $50,000 for equipment. It will conform in style to the present building to which it will be an addition facing Michigan Street. There will be an auditorium seating 500, additional classrooms and laboratories and room to expand the library, for which the last legislature appropriated $20,000 a year for two years for new books. The medical building can accommodate 100 students in each of the three classes, the first year continuing to be taught at Bloomington. The enrolment at the medical school at Indianapolis is about 280 The third building to be erected is a $500,000 nurses' home and training school, a gift of the Ball Brothers of Muncie, to be constructed soon, a little northwest of the Coleman Hospital and southwest of the Riley Hospital. It will be fire-proof, of English Georgian architecture, and connected by tunnel with other medical units, and will accommodate 165 nurses.



William H. Coleman Hospital for Women



New medical school unit

MAINE

State Medical Election.—At the annual meeting of the Maine Medical Association, Portland, June 15, Dr. Herbert F. Twitchell was installed as president; Dr. Frank Y. Gilbert, Portland, was made president-elect. The next meeting will be in Belgrade in June, 1928. A woman's auxiliary was organized during this meeting, and Mrs. Frank Y. Gilbert was elected president.

MASSACHUSETTS

Olives Condemned.—The health department of the city of Boston in its May bulletin notes that large quantities of unwholesome olives have been discovered in the routine examinations of food in Boston. The olives came from Sicily in 300 barrel lots, and on examination were found to be from 15 to 40 per cent wormy; at the time of writing the department had condemned about 1,200 pounds of them.

Personal.—Dr. James S. Stone, Boston, president of the Massachusetts Medical Society, recently addressed the Alabama State Medical Society on "Some Lesions of Bones and Joints in Children."——Dr. Robert C. Stickney tendered his resignation as member of the board of health of Beverley, April 25.——Dr. Charles J. White has resigned as Edward Wigglesworth professor of dermatology at the Medical School of Harvard University, effective September 1, when he will become emeritus professor.

Dr. Wilinsky to Assist in Health Survey of Palestine.—The international commission in charge of a project to survey and study the health of Palestine under the direction of Dr. Milton J. Rosenau of Harvard University Medical School has selected Dr. Charles F. Wilinsky, deputy commissioner of health of Boston, to assist in the survey. Dr. Wilinsky, who has been granted a leave of absence by the city for this purpose, left Boston, May 12, to sail from New York. Since 1916, Dr. Wilinsky has been in charge of the health unit work of Boston, and his appointment is considered by the local health department a recognition of his work on disease prevention.

MINNESOTA

University News.—All students at the University of Minnesota will be given free medical examinations beginning in the fall; at the commencement, June 13, the degree of master of science in surgery was given to Drs. Gilbert C. Anderson, Paul G. Flothow, Norman C. Ochsenhirt and William W. Sager, fellows of the Mayo Foundation. Other fellows receiving advanced degrees were Drs. Herbert V. Dobson and Louis E. Prickman, masters of science in medicine; Dr. Harold D. Caylor, master of science in pathology, and Dr. Dewey R. Heetderks, master of science in otolaryngology. The degree of Ph.D. in surgery was conferred on Dr. Winfred H. Bueermann, now of Portland, Ore., in absentia.

MISSISSIPPI

Ex-Presidents' Club Organized.—During the annual meeting of the Mississippi State Medical Association, the Ex-Presidents' Club was organized with Dr. Peter W. Rowland, chairman, and Dr. Dudley Jones, secretary; eighteen of the twenty-four living ex-presidents of the state society were present. The oldest member is to be chairman of the club automatically, and the active president of the state medical society is to be the annual guest of honor. The object of the club is to promote good fellowship and encourage attendance at the state meeting. There are to be "no dues and no politics."

Society News.—Among others, Dr. Ewing F. Howard addressed the Isaquena-Sharkey-Warren County Medical Society, Vicksburg, June 14, on "Medical Ethics."——At the June 7 meeting of the South Mississippi Medical Society, Hattiesburg, Dr. Wiley D. Forbus, Johns Hopkins Hospital, Baltimore, was guest of honor. Alumni of the South Mississippi Infirmary served a dinner during the meeting, the proceeds of which were donated to a nurse suffering from pulmonary tuberculosis.——Dr. Waller S. Leathers of Vanderbilt University School of Medicine, Nashville, Tenn., addressed the Social Workers Conference at the University of Mississippi, June 23, on "Health Problems and Health Work in the South."——Among others, Dr. Charles M. Coker, Eden, addressed the Central Medical Society, Jackson, May 24, on "Why Doctors Don't Locate in the Country," and Dr. Orrin H. Swayze, Yazoo City, on "Acute Dilatation of the Stomach Following Operations."

MISSOURI

Hospital for Crippled Children Opens.—The state hospital for crippled children at Columbia will begin receiving patients, July 11. The requirements for committing children to the hospital are that the county court appoint a physician to examine the children and make a written report stating whether the condition found can probably be relieved, and that the parents are unable to provide means for suitable treatment. When such certificate has been filed, the court will conduct a hearing to which the parents will be summoned, and if it is found that the preliminary legal requirements have been fulfilled, will order the children to the hospital. The physician is allowed a fee of $5 for the examination of the child and the execution of the certificate to be filed with the court. Dr. Frederick A. Jostes, St. Louis, has been appointed full-time director of the service for crippled children at the state university hospital. Dr. Jostes is at present on the orthopedic staff of the Washington University Medical School, and formerly was on the staff of the Shriners' Hospital for Crippled Children at St. Louis. He has done postgraduate orthopedic work in this country and abroad. The legislature has appropriated $35,000 for the care of crippled children at the hospital during the next eighteen months, and the appeal of this work to the public probably will result in donations by private citizens. Already Mr. J. Dozier Stone of Columbia has informed the board of curators that he will provide funds for establishing a dental clinic in memory of his father and mother Inquiries in connection with this new service will be received by Dr Guy L Noyes, dean of the University of Missouri School of Medicine, Columbia

NEW YORK

Meharry Medical College Recognized.—Meharry Medical College, Nashville, Tenn, has been granted recognition by the New York Board of Regents, it is reported Meharry Medical College has been rated in Class A by the Council on Medical Education and Hospitals of the American Medical Association since January, 1923

Society News—Dr Joseph Ivimey Dowling has been elected president of the Eastern Eye, Ear, Nose and Throat Association, which comprises specialists from Albany, Schenectady, Troy, Glen Falls Amsterdam, Gloversville and Rutland, Vt Dr Morris S Lord was elected vice president, and Dr L Prescott Brown secretary-treasurer

Hospital News—The Williamsburg Hospital and the Brooklyn Eye and Ear Hospital will merge about July 1, and will be known as the Brooklyn Eye and Ear Hospital The present home of the Williamsburg Hospital will be sold and it is proposed to use the funds to assist in the construction of a new building at Green Avenue and Cumberland Street, Brooklyn

Erie County Picnic—The Medical Society of the County of Erie held its annual basket picnic, June 23, on the state hospital grounds near Gowanda Physicians in the entire part of western New York, their wives and children were invited The medical superintendent of the hospital, Dr Earle V Gray assisted with the arrangements, placing tennis courts a golf course, fishing ponds, bowling greens and a baseball diamond at the disposal of the guests The scientific program was a demonstration of the results of the treatment of general paralysis by malaria, an outline of the method of committing a patient to the state hospital, and an exhibition of the occupational therapy and physical therapy departments of the hospital

New York City

Society News—Dr John J Masterson was elected president of the Medical Society of Bay Ridge, June 14——The Medical Society of the County of Kings has acquired the four story building at the corner of Atlantic Avenue which adjoins its present building on Bedford Avenue paying, it is reported, $95 000 the society now owns property facing 100 feet on both avenues

Physicians' Golfing Association—The first tournament of the Physicians' Golfing Association was held at the Rye Country Club, June 10 Dr Frank C Carr won the low gross prize with a score of 83, and Dr John G W Greeff the low net prize with a score of 71 The officers are Dr Wendell C Phillips, honorary president, Dr Anthony Bassler, president, and Dr Harold M Hays, secretary-treasurer There will be four tournaments a year The membership is composed of physicians practicing in Manhattan who are members of clubs in the metropolitan district

Personal—Dr Isador W Kahn has been appointed assistant professor of gynecology at the New York Post-Graduate Medical School and Hospital——Dr Joseph H Gettinger was guest of honor at a dinner, June 17, at the Concourse Plaza Hotel, to celebrate his promotion to visiting physician to the pediatric service in the Bronx Hospital——Dr Alexis Carrel of the Rockefeller Institute for Medical Research has been elected a corresponding member of the French Academy of Sciences——Dr Emil Mayer was elected to honorary membership in the American Rhinological, Laryngological and Otological Society at the recent annual meeting in Atlantic City

Clinics for Treatment of Thrombo-Angiitis Obliterans.—At a meeting of the Committee on Thrombo Angiitis Obliterans, June 16, it was decided to establish clinics in various sections of the country for the treatment of thrombo angiitis obliterans The following hospitals in New York have arranged to establish clinics Polyclinic Hospital, Monday, Wednesday and Friday, 10 to 11 a m, Hospital for the Ruptured and Crippled, daily, 3 30 to 5 p m, Orthopedic Clinic, New York University and Bellevue Hospital Medical College, Monday, Wednesday and Friday, 3 p m A unified chart is being prepared that will facilitate keeping the history and records of these cases and make it possible to check the methods of treatment proposed The charts will be furnished to any physician or hospital wishing to cooperate in this study on request to Dr Benjamin Jablons, secretary of the committee, 90 East Riverside Drive Dr Reginald H Sayre was elected chairman of the committee at this meeting, and Dr Charlton Wallace, treasurer.

Purchase of Rare Medical Library.—The faculty and alumni of Columbia University College of Physicians and Surgeons are raising a fund of $35,000 to obtain the collection of rare medical books that belonged to the late Dr George S Huntington, an alumnus of the medical school and for many years the professor of physiology The library is to be presented to the medical center now under construction at Broadway and One Hundred and Sixty-Eighth Street, where it will be available to the profession and will be known as the George S Huntington Memorial Library Many of these books and manuscripts have no duplicates Among the 4 424 volumes are 780 published prior to the year 1800, and 550 volumes published between 1800 and 1850 This is the first time the faculty and alumni of the school have been requested to contribute to the new medical center, and the fund raised will be turned over to Dr Huntington's estate The memorial committee includes Dr Frederick Tilney, professor of neurology, Dr William Darrach, dean of the medical school, and Dr. Samuel W Lambert, president, New York Academy of Medicine

OHIO

Board of Trustees Commended—The house of delegates of the Ohio State Medical Association, at the recent Columbus meeting, adopted a resolution commending the board of trustees of the American Medical Association and the special committee on physical therapy for their effort to clarify, evaluate and standardize the present problems in respect to physical therapy

Society News—Dr Vilray P Blair, St Louis, addressed the Toledo Academy of Medicine, June 3, on 'Surgical Repair of Congenital and Acquired Defects of the Face," and Dr Chester W Waggoner, Toledo, on "Medical Economics", eight members of the academy were requested to talk on medical subjects before the Woodward High School, June 2-3 This was the first assignment under the new speakers' bureau

Dr Cummer Resigns—Dr Clyde L Cummer, associate professor of clinical pathology, Western Reserve University School of Medicine, Cleveland, has resigned after nineteen years' service at the university Dr Cummer has engaged in the practice of medicine since 1908, and is the author of a manual on clinical laboratory methods He was president of the Cleveland Medical Library Association in 1923 and for several years the treasurer

Unlicensed Healers Arrested.—The Ohio State Medical Board caused the arrest in April of three alleged psychic healers on charges of practicing medicine without a license They were John Wolf, Mrs Mildred Morrison and Mrs Carrie Corp all of Columbus Wolf and Mrs Morrison are alleged to have treated Frank A Dorsey, one of the board's investigators They were each fined $200 by Judge Miller and sentenced to sixty and thirty days in the workhouse, respectively Mrs Corp, C J Wohlgumuth and C W Ferguson were each fined $100 and costs for practicing medicine without a license J T Armstrong, Wellsville, was fined $25 and costs, and E W Sherwood, D O Watts and H B Whitesel, Bowling Green, were also fined in January for illegal practice

TENNESSEE

Personal—Dr James K P Blackburn, Pulaski, has been appointed a member of the state board of medical examiners to succeed Dr Fountain B Hulme——A E Godwin has resigned as assistant secretary of the Vanderbilt University School of Medicine, Nashville, it is reported

Health at Knoxville—Telegraphic reports from sixty-seven cities with a total population of about 30 million to the U S Department of Commerce, for the week ending June 4, indicate that the highest mortality rate (20 4) was for Knoxville The mortality rate for the group of cities as a whole was 11 8

Society News—Dr Seale Harris, Birmingham, Ala, addressed the Chattanooga and Hamilton County Medical Society, June 9, on "Dangers of State Medicine"——The Nashville Academy of Medicine and Davidson County Medical Society held five meetings during May at which, among others, Dr Charles L Hill read a paper on "Erysipelas", Dr Oval N Bryan on "Tularemia" and Dr George K Carpenter on "Unusual Epiphyseal Affections——Dr Oliver W Hill addressed the Knox County Medical Society, May 24, on "Observations on the After Effects of Intracraneal Hemorrhage in the New-Born"; Dr. Marvin F. Haygood addressed the society, May 17, on "Study and Comparison of Knoxville's Typhoid Prevalence During the Last Twenty Years."——The Lauderdale County Medical Society, May 5, was the guest of the physicians of Ripley at the Jefferson Davis Hotel at a dinner.——Dr. Ambrose L. Jones, Greenback, addressed the Blount County Medical Society, recently, on "Treatment of Bronchopneumonia."——Dr. Horton R. Casparis, professor of pediatrics, Vanderbilt University School of Medicine, Nashville, addressed the May meeting of the Williamson County Medical Society on "Early Diagnosis of Tuberculosis in Children."——The medical societies of Monroe, Luden and Roane counties will hold joint meetings during June, July and August.

VIRGINIA

Personal.—Dr. Fred J. Wampler, who recently returned from China, has been appointed health officer for Accomac and Northampton counties, succeeding Dr. Robert P. Cooke, who is now in charge of similar work in Lexington and Rockbridge counties.——Dr. Edith J. Lacy has resigned as assistant physician at the Eastern State Hospital, Williamsburg; the *Virginia Medical Monthly* states that Dr. Lacy expects to go to India for medical service.

University News.—At the commencement of the Medical College of Virginia, Richmond, May 31, eighty-nine graduates received degrees of doctor of medicine; thirty-two were commissioned in the Medical Officers Reserve Corps, U. S. Army. The commencement address was delivered by Dr. Hugh S. Cumming, Surgeon General, U. S. Public Health Service, on "Relation of the Physician to the Public." Dr. Cumming is a graduate of the University of Virginia Department of Medicine, Charlottesville, and of the Medical College of Virginia; he was awarded the honorary degree of doctor of science at this commencement, the first nonprofessional degree to be awarded by the college.

Society News.—The annual meeting of the Walter Reed Medical Society of Virginia was held, May 26-27, Yorktown, under the presidency of Drs. John W. C. Jones, Newport News. The speakers from other states included Drs. John T. King, Jr., Baltimore, "Bedside Aspects of Cardiac Arrhythmias"; Charles R. Austrian, Baltimore, "Early Diagnosis of Pulmonary Tuberculosis"; Emil Novak, Baltimore, "Newer Aspects of Endocrinology and Organotherapy in Gynecology"; Guy L. Hunner, Baltimore, "Ureteral Strictures"; Howard Root, Brookline, Mass.; "Diabetic Problems in Practice"; William B. MacNider, Chapel Hill, N. C., "A Study of Chronic Nephritis"; James F. Mitchell, Washington, D. C., "Treatment of Some Common Infections," and Edwin A. Merritt, "Value of the Graham Technic in Study of Gallbladder Disease." Dr. William W. Kerns, Bloxom, is the new president of the society; Dr. Landon E. Stubbs, secretary, and Dr. James E. Marable, treasurer, both of Newport News.——The Augusta County Medical Society made a donation, May 4, of $100 for the relief of flood sufferers in the Mississippi Valley.——The Walter Reed Medical Society at its annual meeting in Yorktown, May 26-27, appropriated $100 to the Walter Reed Memorial Fund.——The Russell County Medical Society has been reorganized after a period of inactivity, and Dr. Thomas T. McNeer, Dante, was elected president.——Dr. Charles S. Dodd, Petersburg, was elected president of the Virginia Society of Otolaryngology and Ophthalmology at the recent annual meeting; it was decided at this time to award a prize every year for the best paper presented by a member of the society.

WASHINGTON

Hospital News.—The Minor Hospital, Seattle, has announced plans to construct a $600,000 addition.——Dr. Robert J. Kearns, Spokane, has been elected president of the staff of Sacred Heart Hospital.

Personal.—Dr. Charles L. Dixon, Renton, has been appointed health officer of King County, and Dr. Nathaniel E. Roberts, Olympia, has been made health officer of Thurston County to succeed Dr. John J. O'Leary, resigned.

Society News.—Dr. Harry Gaylord Willard, Tacoma, president of the state medical association, lead another "medical caravan" to the Clallam County Medical Society, Port Angeles, May 7; among the speakers were Drs. Willard and John Warren Bell, Everett; Adolph O. Loe, Seattle, and Mr. Robert O. Jones, Seattle, secretary of the Washington Public Health League.——The Pierce County Medical Society, Spokane, voted to publish in three daily papers twice a year, thus giving one list every two months, cards showing the members of the society in good standing. The publicity committee reported at its meeting that the telephone company would not carry their publicity advertising as had been done during the last year. Dr. Joseph F. Griggs, Tacoma, addressed this meeting on "Cardiovascular Renal Disease"; the society then adjourned for the summer vacation.——The Western Branch of the American Urological Association will hold its annual meeting, July 5-7, at Portland, Seattle and Vancouver. The speakers from other sections of the country will be Bernard G. Scholefield, Boston, "Tuberculosis of the Kidney"; Dr. William H. von Lackum, Rochester, Minn., "Data on the Infected Prostate"; Dr. Harold L. Morris, Detroit, "Bilateral Renal Calculi"; Dr. Elmer Hess, Erie, "Renal Sympathectomy." The society will meet at St. Vincent's Hospital, Portland, the Medical and Dental Building, Seattle, and the Vancouver General Hospital, Vancouver.——Physicians from Skagit, Whatcom and Snohomish counties held a joint scientific meeting, golf tournamount, and banquet at the President Hotel, Mount Vernon, June 8.

WISCONSIN

Enlarged Program for Postgraduate Study.—A two year program of medical extension work at the University of Wisconsin, has been announced following a joint meeting of representatives of the state medical society, the state medical school and the extension division of the University of Wisconsin. The program has four fields of effort: (1) medical literature and case report service for individual physicians; (2) lecturers for county medical societies, the programs to be supplied without expense; (3) postgraduate courses at the university; (4) special lecture-clinical groups. About $18,000 will be expended on this work. At a subsequent meeting it was decided that the work would be offered under the joint auspices of the state medical society, the medical school and the extension division of the university. The executive committee comprises Chester D. Snell, of the extension division; Dr. Arthur W. Rogers, president of the state medical society; Dr. Charles R. Bardeen and Joseph S. Evans, of the medical school, and Mr. J. G. Crownhart, ex officio. The package library service will be enlarged and a full-time medical librarian employed. The state medical journal will publish a special section on case reports. It will be possible for every county medical society to have the services of members of the staff of the medical school and others as speakers without cost. Requests for program material should be made to Dr. Robin C. Buerki, Wisconsin General Hospital, 1300 University Avenue, Madison. Requests should be preferably on the basis of subjects desired rather than for individual lecturers. The short review courses to be offered by the university medical school will become effective in 1928 and will be in the field of remedial agencies. The lecture-clinical groups will be organized on the North Carolina Plan and become effective in 1928.

GENERAL

Changes in Cuban Journal.—*Vida Nueva*, the Havana journal founded and edited by the late Dr. D. Tamayo, formerly Cuban secretary of public health, is now edited by Drs. O. Montoro and I. Castellanos. The old policy of limiting the scope of the journal to social-medical questions has been abandoned, and instead each issue will be devoted to one important medical subject, as French journals are wont to do. The abstract department has been enlarged and systematized and the number of pages increased; the publication is, in general, more attractive. The subscription price is $5.

Society News.—Dr. John F. Barnhill, Indianapolis, was elected president of the American Laryngological, Rhinological and Otological Society at the recent annual meeting in Atlantic City, and Dr. Robert L. Loughran, 33 East Sixty-Third Street, New York, secretary.——The thirty-second annual meeting of the National Medical Association will be at Detroit, August 15-19, under the presidency of Dr. Carl G. Roberts, Chicago; although many social features have been arranged, the journal of this association states that the dominant note will be "professional progress." All of Wednesday will be devoted to clinics and demonstrations in all the sections.

Renewal of Permits Under National Prohibition Act.—Physicians holding permits under the National Prohibition Act entitling them to prescribe and use intoxicating liquor who desire to retain those privileges during 1928 must file renewal applications on or after July 1, but not later than August 31. Application should be filed with the prohibition administrator having jurisdiction over the district in which the physician practices. For good cause shown, the prohibition administrator may grant an extension of time for filing application, but the granting of such an extension is entirely discretionary with that official, and in no case may the time limit be extended beyond November 30. Physicians failing to make timely application must thereafter apply as for a new permit, if permit privileges are desired. Applications should be submitted in triplicate on forms which will be supplied by the prohibition administrators.

Joint Postgraduate Conference in October.—The annual fall conference of the Kansas City Clinical Society will merge with the 1927 session of the Inter-State Post-Graduate Assembly of North America at Kansas City, October 14-22; this will be the fifth year that the Kansas City Clinical Society has provided a clinical conference, and will conclude its fifth year program to develop the educational advantages of clinical material in Kansas City. The joint session in October will bring together at least eighty clinicians from various countries to hold clinics in the specialties, to present symposiums and to give addresses and demonstrations. The joint meeting will be at the Ararat Shrine Temple, Eleventh and Central streets, Kansas City, Mo. The entertainment program will include alumni dinners, smokers, receptions, automobile drives and a banquet to the guests. The general chairman of the Kansas City Southwest Clinical Society is Dr. E. H. Skinner, 631 Rialto Building, Kansas City, Mo.

"Drinking" Now Adulterates Oysters — Former Decision Repealed. — The department of agriculture has repealed a decision which was issued in 1910. The former decision held that it was not illegal to drink oysters in waters of saline content equal to that in which the oysters will grow to maturity, and that oysters floated in water of less saline content than that in which they will properly mature cannot be considered adulterated if the packages containing them are clearly labeled "floating oysters." The department holds now that the floating or drinking of oysters, as practiced under the former decision, has the effect of adulterating them with water, and the interstate shipment of oysters so adulterated constitutes a violation, even though they are labeled "floating oysters." The department will, therefore, proceed, under the terms of the Food and Drugs Act, against all shipments of oysters whether shucked or in the shell which have been adulterated by floating or other means.

FOREIGN

International Conference on Goiter at Berne.—Under the auspices of the Swiss Goiter Committee, an international conference on goiter will be held in the aula of the university building in Berne, Switzerland, August 24-26. The president of the conference, Dr. H. Carrière, will give the opening address on the general distribution of goiter, and among other speakers will be Prof. L. Aschoff, Freiburg; Dr. David Marine, New York; Professor de Quervain, Berne; Dr. McCarrison, Cooroon, India; Professor Galli-Valerio, Lausanne, and Prof. Wagner von Jauregg, Vienna. The assembly will be welcomed by the officials of the canton and the city of Berne. There will be a demonstration in the surgical clinic by Prof. F. de Querin, August 27, and in the afternoon a trip to the poor farm with a demonstration of cretins. The conference was first planned by the Swiss Goiter Committee in 1923, and had to be postponed until this year.

Postgraduate Courses in Berlin.—The association of professors, in collaboration with the organization representing the Kaiserin Friedrich Institute and with the medical faculty of the University of Berlin, has organized international postgraduate courses in medicine to be held in Berlin. There will be continuous courses extending over the greater part of the year, and courses held only from September 15 to October 31. The two types of continuous courses are (1) individual courses in all branches of medicine, with opportunities for practice, usually covering four week periods, and (2) so-called externships in clinics, hospitals and laboratories, chiefly intended for medical men seeking practice as assistants for longer periods. The short courses are general courses in all branches of internal medicine, with emphasis on therapy. There will also be short courses for nose, ear and throat specialists. The medium of instruction is German, although many teachers are able to instruct in English, French or Spanish. Further information may be obtained by addressing Kaiserin Friedrich Stiftung, Kaiserin Friedrich Haus, 2-4, Luisenplatz, Berlin, NW 6.

Government Services

U. S. Public Health Service

Surgs. Joseph W. Mountin, Jefferson City, Mo., Knox E. Miller, New Orleans, and Asst. Surg. Erval R. Coffey, Jefferson City, Mo., and Acting Asst. Surg. Winfield K. Sharp, Jr., Nashville, Tenn., and Associate Sanitary Engineer A. L. Dopmeyer, Memphis, Tenn., were recently ordered to duty to cooperate with the state and local health authorities in connection with the prevention of epidemic diseases in the flooded areas of the Mississippi Valley, and Asst. Surg. Raymond A. Vonderlehr and Surg. Randolph M. Grimm, both of New York, have been assigned to duty at the hygienic laboratory, Washington, D. C.——Surg. Peter J. Gorman has been relieved from duty at Ellis Island and directed to proceed to duty at Nogales, Ariz., assuming charge of activities there.——Surg. Joseph Goldberger was directed to proceed from Washington to Milledgeville, Ga., then to Dallas, Texas, and return in connection with pellagra studies.——Dr. Mather H. Neill has been relieved from duty at Honolulu and assigned to duty at marine hospital number 19, San Francisco.——The following officers have been ordered to duty at the stations indicated after their names: Surg. Newton E. Wayson to Honolulu to assume charge of the U. S. Leprosy Investigation Station; P. A. Surg. Ralph L. Lawrence to Washington, D. C., and report to the Surgeon General for duty. Asst. Surg. John F. G. Gates to U. S. Quarantine Station, New Orleans; Asst. Surg. George G. Holdt assigned to duty at U. S. Marine Hospital number 19, San Francisco, Calif.; Surg. Harvey G. Ebert, directed to proceed to Providence, R. I., and assume charge of service activities at that station; Surg. Herbert M. Manning, directed to proceed to Marcus Hook, Pa., to assume charge of the U. S. Quarantine Station; Surg. Harry E. Trimble assigned to duty at U. S. Marine Hospital number 7, Detroit; Asst. Surg. F. S. Fellows, assigned to duty at U. S. Quarantine Station, Rosebank, S. I., N. Y.; Surg. Marion S. Lombard, directed to proceed to Key West, Fla., and assume charge of U. S. Marine Hospital number 10; Asst. Surg. Albert T. Morrison, assigned to duty at U. S. Quarantine Station, Angel Island, Calif. The following reserve officers have been ordered to duty: Asst. Surg. Ralph Horton to U. S. Marine Hospital number 1, Baltimore; Asst. Surg. Clarence D. Kosar to Washington, D. C., and return for conference at the bureau; Asst. Surg. Fred W. Caudill, assigned to duty at U. S. Marine Hospital number 3, Buffalo Surg. C. P. Knight has been directed to proceed from the Canal Zone to Washington, D. C., to report to the Surgeon General for duty.——Surg. G. W. McCoy has been directed to proceed from Washington, D. C., to Rockford, Ill., in connection with field investigations of smallpox.

Changes in Veterans' Bureau Personnel

The May issue of the U. S. Veterans' Bureau Medical Bulletin reports the following changes in personnel:

Dr. Edward R. Anthony, Jr., resigned at Memphis, Tenn.
Dr. Clifford C. C. Brace, appointed at North Chicago.
Dr. William C. Davis, transferred from Tupper Lake, N. Y., to Fort Bayard, N. M.
Dr. John L. Donahue, reappointed at Fort Bayard, N. M.
Dr. Morris H. Goodman, transferred from Washington, D. C., to St. Cloud, Minn.
Dr. Mansell B. Holmes, appointed at North Little Rock, Ark.
Dr. John H. Kay, resigned at North Little Rock, Ark.
Dr. Claude C. Keeler, transferred from St. Paul to Fort Snelling, Minn.
Dr. David Kramer, resigned at Fort Bayard, N. M.
Dr. Louis S. London, resigned at Bronx, N. Y.
Dr. Herbert O. Matthews, appointed at Tuskegee, Ala.
Dr. Rob Roy McCully, reappointed at Rutland Heights, Mass.
Dr. Frank W. Schwarz, transferred from Legion, Texas, to Perry Point, Md.
Dr. George M. Shewalter, transferred from Outwood, Ky., to Aspinwall, Pa.

REGIONAL OFFICES

Dr. Charles R. Bird, resigned at Indianapolis.
Dr. Edward W. Finn, resigned at Boston.
Dr. Jasper E. Guernsey, appointed at Helena, Mont.
Dr. Ralph R. Harris, resigned at Cleveland.
Dr. Mansell B. Holmes, resigned at Dallas, Texas.
Dr. Warner L. Lindsay, resigned at Salt Lake City.
Dr. Frank E. McClane, resigned at Detroit.
Dr. Carl W. McGaughey, transferred from Cincinnati to Chicago.
Dr. Albert J. Weirick, resigned at Chicago.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 25, 1927.

Ernest Henry Starling

The death of Ernest Henry Starling, C.M.G., M.D., F.R.C.P., F.R.S., Foulerton research professor of the Royal Society, while on a voyage for his health in Jamaica, removes one of the greatest physiologists of the world, whose work on the internal secretions was epoch-making and on the circulation of the first importance. After a brilliant career at Guy's Hospital, he graduated in medicine in the London University in 1888. He continued his studies at Heidelberg under Kuhne, and became demonstrator of physiology at Guy's in 1889 and joint lecturer in the following year. He studied under Heidenhain at Breslau, which led him to take up the study of lymph formation. In 1889 he succeeded Schäfer as professor of physiology at University College, London. There he not only taught physiology but made most of the researches which have made him famous. Much of his work was done in collaboration with his brother-in-law, William Bayliss, also a great physiologist. Starling's interest in physiology was general, but those physiologic processes which seemed susceptible of interpretation in terms of chemistry and physics most attracted him.

His first paper, written with Bayliss in 1891, was on electromotive phenomena of the mammalian heart. Waller had recently studied the electrical variation of the heart. Starling thought that, by photographing the movements of the capillary electrometer connected with electrodes placed in different positions on the naked heart in the anesthetized animal, much might be learned of the nature of the cardiac contraction. At that time any sort of muscular continuity between the auricles and the ventricles was denied, and the view that conductivity was due to some nervous network supplying the fiber was in favor. Bayliss and he set out to ascertain the course and time relations of the wave of contraction in the ventricle, the nature of the transmission from auricle to ventricle, and throughout the ventricle. They showed that (1) the ventricular contraction is a single wave starting from the base; (2) there is a natural block at the auriculoventricular groove, and (3) the rate of transmission of the contraction wave is about 5 meters a second. They thus made an important advance in our knowledge of cardiac contraction. They next investigated the action of the vagus and accelerator nerves on the auricles, on the ventricles, and on the conducting power of the auriculoventricular junction in the mammal. The effects of these nerves on the heart of frogs and tortoises had been previously studied by Gaskell and Heidenhain, and that of the vagi on the auricle of mammals. Bayliss and Starling showed that there was no essential difference between mammals and cold-blooded animals; that the vagus depresses conduction in auricle, auriculoventricular junction, and ventricle; and that the accelerator nerves have the opposite effects. They next made an exhaustive study of the simultaneous changes in the arterial and venous pressures of various regions of the body under a great variety of experimental conditions and showed the universal applicability of the principle of the circulation worked out by Ludwig.

In 1892, Starling investigated the mechanism of lymph flow. At first he adopted the interpretation of Heidenhain that the lymph formation could not be explained by filtration and that it was necessary to suppose a selective activity of the vessel wall. But later he came to the conclusion that it was unnecessary to assume a secretory activity of the endothelium, and that there was no experimental fact inconsistent with the view that lymph formation was a function of two factors—permeability of the vessel wall and intracapillary pressure. But to these he had afterward to add another factor—the osmotic pressure of the colloids, to which the walls of the capillaries are relatively impermeable. He showed that hydrostatic pressure and osmotic pressure with altered permeability of the endothelium can explain edema and pleural effusion. His work with Bayliss is an important advance. He showed that (1) peristaltic contractions are coordinate reflexes carried out by the local nervous mechanism and independent of the central nervous system; (2) local stimulation of the intestine produces excitation above, inhibition below, and (3) besides the local mechanism, every part of the intestine is subject to the control of the central nervous system through the splanchnics and vagi, the former being inhibitory and the latter containing both augmenting and inhibitory fibers.

Next came their epoch making work on pancreatic secretion. They discovered secretion, and this led to the introduction into physiology by Starling of a new conception—that of "hormones," or "chemical messengers." This work culminated in his Croonian lectures to the Royal College of Physicians in 1905 on the chemical correlation of the functions of the body. In 1909 he returned to the subject of his earliest work—the physiology of the heart. He devised his now famous "heart-lung preparation," in which the lesser circulation is intact but the only paths from the left ventricle to the right auricle are through the coronary arteries, and an artificial connection in which the resistance can be regulated. He showed that cardiac muscle, like voluntary muscle, contracts more forcibly as it is stretched even up to the point at which the texture is fractured. Therefore, to work at greatest efficiency a heart must first dilate, which it inevitably does, as the pressure in front of it increases. This Starling called the "law of the heart." In his Harveian oration of 1923 he said: "The heart has thus the power of automatically increasing the energy evolved at each contraction in proportion to the mechanical demands made upon it, behaving in this way almost like a sentient, intelligent creature." In 1920, with Anrep, by an ingenious cross-circulation method, built up on his heart-lung preparation, he showed that whereas rise of aortic pressure leads to dilatation of the blood vessels as long as the depressor nerves are intact, change in the blood pressure in the supply to the brain produces the reverse change in the pressure of the rest of the body. These fundamental laws of regulation had been suspected but never before established.

Fatal Administration of Carbon Dioxide in Mistake for Nitrous Oxide

An inquest was held by the deputy coroner for the city of London, on the body of a woman, aged 35, who died in St. Bartholomew's Hospital. An anesthetic was given to the patient for an operation, and a few minutes later she showed signs of failure. Efforts to restore animation, including heart massage, were tried for seventy-five minutes, without success. Sir Bernard Spilsbury, who made a necropsy, stated that the woman was quite healthy, and the operation that she was to have had was often quite successful. The cause of death was asphyxia from carbon dioxide gas, which was given sometimes in small quantities as a stimulant. The anesthetist said that he began with gas and oxygen and turned on carbon dioxide instead of nitrous oxide gas. He used 80 parts of carbon dioxide to 20 parts of oxygen, instead of 80 parts of nitrous oxide to 20 parts of oxygen. The dioxide cylinders were painted green down the sides and black on top, and his mistake occurred through his standing up and looking at the cylinder from above instead of from the side. To the question of the coroner as to whether the mistake might have occurred at other times he replied in the affirmative and suggested that the cylinders should be green right up to the top and that there should be a different tap. The anesthetist added that he realized his mistake in three minutes, and before the patient was moribund, and he at once asked for strychnine. Everything possible was done for her. During the past twenty years he had given about 20,000 anesthetics. Recording a verdict of "death from misadventure" the coroner said that the anesthetist admitted that he made a mistake and there was no evidence of negligence.

The Prevention of Diphtheria

A report on "The Prevention of Diphtheria," by Dr. J. Graham Forbes has been issued by the Medical Research Council. It was originally prepared from the information of the Public Health Committee of the London County Council, and is a comprehensive survey of the methods for the prevention of diphtheria which have been practiced on a large scale during the past ten years in America, and to a much less, though growing, extent in Great Britain. The antitoxin treatment of the disease brought down the case mortality quickly from 30 to below 10 per cent, but since 1904 the decline, though continued, had only been from about 9 to about 7 per cent. During the whole time of the use of this method the attack rate and the virulence of the disease had been increasing. In London, for instance, between 1904 and 1924 the attack rate per thousand persons living rose from 11.2 to 19.1, and the deaths from 0.99 to 1.33. The cost of applying to the 620,000 children of the London schools the Schick test for diphtheria and prevention of the disease by active immunization would be $500,000, inclusive of extramedical service which might amount to $425,000. During 1921 the cost of diphtheria alone to London taxpayers was estimated at about $2,500,000 and the cost of every case of diphtheria at about $150, a sum which would cover the cost of protecting 200 children. After analyzing the results of preventive work in Great Britain and also for many countries abroad the conclusion is reached that the Schick test and immunization constitute one of the most notable advances in preventive medicine. Their systematic adoption would result in a great yearly saving of child life, notably in London, where though diphtheria has been more generally prevalent and presents a more pressing and difficult problem than in the provinces, no coordinated effort has been made to introduce immunization. The problem calls for the closest cooperation of all authorities concerned, whether public health, administrative or educational, particularly in London, where, for diphtheria, the attack rate surpasses, and the mortality rate nearly so that of any other city in Great Britain, and almost every other capital in Europe, if not the world.

Medical Research in the Colonies

At the recent colonial conference, especial attention was given to medical research and medical education, to the training of natives as dispensers and sanitary officers, and the training of native women as general nurses and workers at child welfare centers. The provision of efficient sanitary services, including European and native inspectors, was also discussed. There are now medical research institutes more or less adequately staffed in the West African, East African, Middle Eastern, and Far Eastern groups of colonies, and in the main the colonial governments are alive to the importance of medical research, and within the limit of their resources are giving it adequate support. There is need, however, for more effective contact between research workers in the tropics and those engaged in similar activities in Great Britain and other countries, especially as it is becoming recognized that medical research has no colonial boundaries and that research in the tropics may have an important bearing on disease problems in temperate zones.

Statistics on Cancer of the Tongue at the Fondation Curie

MM. Roux-Berger and Octave Monod have collected statistics on cases of cancer of the tongue, in which treatment by radium and by roentgen rays was given at the Fondation Curie, from Jan. 1, 1920, to Dec. 31, 1925. The report covers 311 cases, 287 of which were studied in the most remote stages. There were seventy-seven recoveries of from one to six years' standing, or an equivalent of 26.7 per cent. Recoveries are becoming more numerous, owing to the progress of technic. Anterior dorsolingual cancers were almost all treated by the introduction of radium; the posterior dorsal cancers by radium, with or without exterior irradiation (the combination of the two methods seeming to give the best results). In some cases, roentgen rays or mere external irradiations were employed, with negative results. In the treatment of infralingual cancers, the use of plaster casts appeared to give the best results. An important improvement in technic consisted in removing them, as far as was feasible, from the maxillary arch to prevent radionecrosis otherwise frequent. A large number of patients classed among the "failures" were cured of their local lesion but developed later glandular metastases. The results of the treatment of adenopathies are much more difficult to appraise, for all the cases in which an operation was not performed leading to recovery remain doubtful, since the inflammatory or neoplastic nature of the glands was not ordinarily verified histologically. Of thirty-seven patients who did not present glands clinically distinguishable, degeneration of glands was noted in seven later. On the other hand, of forty-two evident adenopathies not treated, eleven resulted in recovery. The introduction of radium, though it may effect great improvement, will not of itself cure adenopathy, for it is inapplicable to the small deep-lying glands, which are numerous. Associated with exterior apparatus acting on a surface of skin 7 or 8 cm. wide, it gives better results. But cancericidal doses are difficult to reach and the preferred treatment appears to be a combined radium and surgical treatment.

The Decrease in the Consumption of Alcohol in France

The administration of indirect taxes, which records the imposts collected on alcohol, has issued a report from which it would seem that the consumption of alcohol in France has diminished by 46 per cent in thirty years. According to the statistics cited, the total consumption of alcohol must have decreased by 735,685 hectoliters, and the average per individual by two liters. These results appear due, in part, to the activities of the antialcoholic leagues, but particularly to the greatly increased tax imposed by the state on alcohol. However, the physicians in the hospital services have not observed a diminution in the number of patients whose condition was due to or aggravated by the excessive use of alcohol. M. Achard has even declared that, since the war, alcoholism has appeared to him to be on the increase, especially in women, in whom it was formerly exceedingly rare. There seems to be no other explanation for the discordant views than that the tax on alcohol is in many instances fraudulently evaded, for it is a common observation that fraud develops apace when taxes are raised to a high level. There is in France an unfortunate law on the statute books, the abolition of which has been perseveringly demanded by the hygienists but without avail, which authorizes every producer of wine and cider or grower of fruits to distil 10 liters of brandy each year for his personal use without payment of a tax on it. The law was suspended for a time immediately after the war, during the first enthusiasm for far-reaching reforms. The members of the chamber of deputies, harassed by their constituents, have seen fit to restore the law, although the privilege was reduced to 10 liters. It has been calculated that the privilege is extended to several hundred thousand growers, which allows an immense quantity of alcohol to escape payment of duty. However, while it may be admitted that 46 per cent reduction may not give a faithful conception of the true state of affairs, there has been a notable diminution in the consumption of alcohol in France during the past thirty years.

Anatoxins

Anatoxins, the serums discovered at the Pasteur Institute by Ramon and widely used at present, are toxins attenuated by heating in combination with formaldehyde or sodium palmitate over a water-bath at a temperature of 38 C. for from fifteen to twenty days. They have then lost their toxicity and have become fit to use as vaccines. Antitetanic serum is today prepared in the same manner, and when injected does not cause a serum reaction. M. Vechiu, of the Société de pathologie comparée, has reported numerous observations from which it appears that formaldehyde and sodium palmitate injected in large doses in animals that have been given tetanic toxin do not exert in their organism any attenuating effect on the toxin.

Favus in France

Dr. Jeanselme, professor of dermatology and venereology at the Faculté de médecine de Paris, and Dr. Joannon have presented a communication on favus, or tinea favosa, which had become rare in France before the war, but which is again becoming frequent by reason of the increasing number of cases brought in by foreign immigrants. The latter come chiefly from Poland, Russia, Roumania and Armenia, and, for the most part, are crossing France on the way to the United States, but they are prevented from continuing their journey by the rigorous sanitary control that is imposed in France on these immigrants. Immigrants are sent back to France by the American authorities when, as sometimes happens, they succeed in escaping such control. In that case they become stranded in Paris and are sent to the service of Dr. Jeanselme in the Hôpital St. Louis, in which are centralized all the cases of leprosy discovered among the traveling foreign element This fact is just one more added to the many that go to prove that an energetic sanitary control of immigrants in France is needed such as is demanded unceasingly by Prof. Léon Bernard before the League of Nations, patterned after the American system, although the administration of such a system will be admittedly much more difficult in France because of the long extent of the land frontiers and the ease with which these may be crossed.

Agreement of the Composition of a Product with the Announcements on the Label

The manufacturer of a powder used in the preparation of a table beverage was summoned before the correctional court for having mentioned on the label two products of which according to analytical chemists, there were only "traces" present. The procurator of the department of the Seine had concluded that the products were represented by too small quantities to be designated. The court, however, decided that the defendant had not violated the law of 1905 pertaining to fraudulent practices but, on the contrary, was quite within his rights in mentioning all the substances composing the product, irrespective of the quantity present, minimal though it might be, and rendered a judgment of acquittal.

Information Bureau Regarding Spas and Climatic Resorts

A French information bureau regarding spas and climatic resorts has been opened in Paris, 15 rue Royale (Office *thermal et climatique français*), the object of which is to aid patients, French and foreigners, in the selection of suitable places. The bureau will furnish all information needed in regard to "cures" (cost and nature of treatment). It will without charge reserve rooms in hotels in accordance with requirements and at prices compatible with the resources of each individual. For journeys it will issue special tickets and will provide means of transportation not only to the health resorts but also for drives and excursions. The bureau states that it will endeavor to procure everywhere special terms for physicians and their families.

Complement Fixation in Leprosy

Dr. J. M. Gomes of São Paulo has recently studied the value of several complement fixation tests in leprosy. The Wassermann test is practically useless for diagnostic purposes since leprous serums deviate the complement with a syphilitic antigen almost as well as syphilitic serums. The Kolmer modification and Kahn's precipitation test seem more advantageous as, according to some workers, they are absolutely negative in leprosy. The ideal reaction should be, however, positive for leprosy and negative for syphilis. Dr. Gomes aimed at three objectives: to secure one more agent for early diagnosis; a better differentiation between the two diseases, and a means of showing the coexistence of both leprosy and syphilis. Gomes described a number of his cases to show the advantage gained by treating in such coexistent infections the syphilitic process before instituting treatment for leprosy. His work followed the lines of Dreyer's and Taylor-Malone's experiments on defatting acid-fast bacilli. For his complement fixation tests he used *Streptothrix leproides*, after defatting with olive oil and acetone, according to Mejunkin's technic. Altogether, 167 serums from normal subjects and patients with syphilis, tuberculosis, skin diseases and actual or suspected leprosy were studied. The reaction proved negative in all these conditions, with the exception of leprosy, and a slightly positive result in a case of tuberculosis. In leprosy, the positive results reached 82.29 per cent, distributed as follows: mixed type, 95.23 per cent; tubercular, 88.88 per cent; anesthetic, 87.50 per cent; maculo-anesthetic, 70.37 per cent; fruste forms, 50 per cent. The negative results were mostly among cases either cured or recovering. Among twenty-eight leprosy carriers, a number of them without clinical signs, 37.71 per cent were positive.

Fuchs in Brazil

At the invitation of the Rio de Janeiro medical school, Prof. E. Fuchs of Vienna has come to give a series of lectures on ophthalmology.

Enormous Number of Gallstones in a Patient

Among other interesting disclosures in a patient operated on for gallstones, Prof. Brandão Filho mentions the large number, 1,445, of calculi in the gallbladder. Most were small, but some were as large as hazelnuts. The strangest thing was the complete lack of any signs of pericholecystitis in spite of so many stones. The patient never had jaundice, despite the frequent attacks which reflected the migration of stones. These, however, were small and did not block the common duct with consequent retention of bile.

Uselessness of Steinach's Operation in Parkinson's Disease

In the *Lancet,* some time ago, Walker and Cook reported encouraging results in three cases of paralysis agitans in which Steinach's operation was performed for rejuvenation purposes. Brandão Filho tried the operation in a case of the same disease, with no improvement whatever afterward. Of course, one case is not enough to afford a basis for passing on the merits of any treatment.

The New Cancer Institute

The new Cancer Institute of the Oswaldo Cruz Foundation has all possible equipment. The Laboratory of Scientific Research has all the material necessary for pathologic, therapeutic, surgical and radiologic work. All kinds of animals will also be available, the necessary accommodations being provided for them. The hospital department is divided into two sections: hospital proper and dispensary. The hospital is again subdivided into two sections: roentgen-ray and Curie, devoted to roentgen-ray and radium therapy, respectively. The upper floors have wards for needy patients. The third floor is reserved for pay patients. There is little question as to the new institution being the largest and perhaps best equipped among all those devoted to cancer.

ITALY

(From Our Regular Correspondent)

March 31, 1927.

The Death of Antonio Carle

Italian universities have suffered another loss in the death of Prof. Antonio Carle, director of the surgical clinic of Turin and chief surgeon in the Ospedale Mauriziano of that city. Born in 1855 in the province of Cuneo, Carle was graduated at Turin and continued his studies in Billroth's clinic. His first important researches were studies on tetanus. There followed researches on the circulatory changes in the brain in anesthesia; experiments on typhoid; studies, in collaboration with Lustig, on the etiology of endemic goiter, and studies on benign conditions of the stomach and their treatment by gastro-intestinal lavage. In 1893, he was made professor of special surgical pathology at the University of Turin, and in 1900 he became the director of the Clinica Chirurgica. In addition to numerous monographs on the surgery of the stomach and of the thyroid, he wrote, in collaboration with Herlitzka, the chapter on uterine tumors for the Trattato italiano di chirurgia. He was a member of many scientific academies, national and foreign, and was for many years "*senatore del regno.*"

National Congress of Hydrology and Climatology

The eighteenth Congresso nazionale di idrologia e climatologia will be held in Milan in the early part of October. The two main topics on the program are: (1) the present status of knowledge concerning the action of mineral waters, to be presented by Prof. Adriano Valenti, and (2) the sojourn of tuberculous patients in climatic resorts, with reference to legislation, therapy and hygiene. The leaders in this discussion will be Prof. Ambrogio Da Gradi and Dr. Emilio Silvano.

Opposition to Neomalthusian Propaganda

The new public safety law contains provisions directed against neomalthusian propaganda, and declares that writings, pamphlets, illustrations, and other means that serve to make known methods for the prevention of conception or for the interruption of pregnancy, even though such methods are applied under the pretext of therapeutics or in the name of science, are offensive to morals and good breeding. Likewise, the insertion in newspapers of notices or correspondence pertaining to neomalthusian practices is prohibited.

Vital Statistics

Dr. Molinari has recently published a series of vital statistics on the commune of Milan for the year 1925. The population of Milan, the capital of Lombardy, as of Jan. 1, 1925, was 864,654, exclusive of the garrison. The number of marriages contracted in Milan in 1925 was 6,362, or 7.34 per thousand inhabitants. The total number of births was 12,720 (6,480 males and 6,240 females), or 14.7 per thousand inhabitants. The birth rate (which continues to decrease) is one of the lowest in the large cities of Italy. The birth rate for Rome was 24.75; Naples, 25.43; Turin, 11.94; Genoa, 12.62; Florence, 25.59, and Bologna, 27.16.

The total number of deaths in Milan in 1925 was 11,627, or 13.58 per thousand inhabitants. The death rate in Rome was 16.44; Turin, 15.17; Venice, 18.93.

Provisions for Child Welfare

At recent sessions, the executive committee of the Opera nazionale per la protezione della maternità e dell' infanzia decided to establish in Latium four ambulant chairs of child welfare, to be delegated to trusted physicians of the society. The committee plans to create also a first nucleus of fifty-four obstetric and pediatric advisers in a like number of communes of the realm, together with permanent seaside colonies for the children of government employees, who will pay a low rate, while the major expense is assumed by the welfare society.

An Exposition of Italian Universities

The second exposition of the universities of Italy will be held in Rome in August. At the same time, students from all countries will convene at Rome to take part in the congress of the international confederation of students.

Congress of the German Society of Internal Medicine

(Continuation)

Of the remaining addresses — to the number of about 100 — delivered at the Congress of the Deutsche Gesselschaft für innere Medizin, only the most important can be mentioned. In the field of nervous disease, Hohmann of Cologne spoke on the galvanic method of testing stimulability in organic neuroses. Before psychotherapy is applied, it must be determined to what extent psychic disturbances are the cause and how far peripheral failure of vegetative functions may be incriminated. In organic disorders of purely psychogenic origin, increased stimulability is absent. Such conditions, in contradistinction to cases with increased stimulability, can be cured promptly and permanently by psychoanalysis or suggestion. The researches of Schön of Leipzig, with operative exclusion of controlling portions of the brain, on the rabbit, and analysis of the effect of morphine on the respiration of intact animals operated on, leads to the assumption of the following control centers for respiration: in the posterior portion of the midbrain a stimulable center, and in the thalamus and cerebrum retarding centers acting on the respiration.

Hansen and Gessler of Heidelberg were able, by means of hypnosis, so to change heat regulation in some patients that, when given the suggestion of heat, accompanied by simultaneous cooling, they behaved as if no cooling had taken place. No increase in the consumption of oxygen occurred. On the other hand, when the cooling was omitted and only the suggestion of cold was given, an increase in the oxygen consumption amounting to from 30 to 40 per cent (the effect of a cold douche) was established with the Benedikt apparatus. Kauffmann of Cologne stated that, with endolumbar injection and lavage treatment with a quinine solution he had obtained good results in meningitis and other diseases of the central nervous system. He uses a special type of apparatus. Stahl and Busch of Rostock found as a by-effect of morphine (which could be eliminated by atropine) a reduction of resistance to toxins and a loss of weight in white mice.

Regelsberger of Erlangen reported his researches on the sleep curve in man, as determined by the Trendelenburg apparatus, and stated that there is a high peak just before midnight and another high peak (though not so high) just after midnight; in pathologic cases the reverse condition prevails. Friedberger of Berlin discussed the influence of diet on tumor growth in rats, and stated that a diet consisting of raw foods favored such growth, whereas, on a diet of overcooked food, only 42.9 per cent of the tumors increased in size. With the best food (egg yolk), from the standpoint of the caloric estimate, the tumor growth was also best.

In the field of research on the circulation, Bruhns of Königsberg brought out, following investigations on the elimination of cardiac standstill, that artificial respiration will not produce an emergency circulation. There is too little blood in the left heart and in the arteries, and the reddening of the skin associated with apparent death is due to the filling of the capillaries with venous blood through ejection of blood from the upper abdomen and the thorax. Also massage of the heart was shown to be important. Various medicaments, when injected into the heart, are likewise of value. The combination of heart massage with artificial breathing is needed, and simultaneously inflation with oxygen. For the relief of cardiac standstill Sylvester recommends artificial respiration in combination with rhythmic compression of the thorax and the inflation of oxygen. Schott of Cologne was able in the rabbit to effect partial resuscitation of an isolated heart. An essential factor was the expansion of the heart wall. Also in a dead person, by the intravenous induction of oxygen the heart can be made to beat from two to three hours after the electrocardiogram has ceased to show that the heart is functioning.

Guggenheimer and Fisher (Berlin) reported on the effects of exceedingly dilute solutions of iodine and bromine, which produce in the cat heart distention of the vessels and increased velocity of circulation.

Magnus-Levy and Siebert (Berlin) found in some types of grave nephritis a retention of ammonia corresponding to the gravity of the case and recommend reduction of the protein intake and the administration of basic salts.

Metabolism problems came in for comprehensive treatment. Grafe and Meythaler (Wurzburg) established by their researches that the blood sugar itself checks insulin production and thus constitutes a regulating hormone, to a certain extent. Depisch of Vienna found that the degree of alimentary hypoglycemia represents a measure for the stimulability and performance of the islands of Langerhans. In patients with exophthalmic goiter the islands of Langerhans oppose, to a certain extent, the tendency toward loss of weight. In obesity there are cases that owe their origin to an increased action of the islands.

Deusch of Rostock did not find in 100 cases of diabetes mellitus either clinical manifestations of a disturbance of the external pancreas secretion or any changes in the normal content of ferments as represented by trypsin, diastase and lipase. After intravenous injection of insulin, there resulted an increase of the external pancreas secretion, so that insulin in this respect is an antagonist of epinephrine. The effect is produced through *stimulation of the vagus*. Cobet and Nothmann (Breslau) found insulin in the urine of healthy subjects every day in quantities equal to from 15 to 30 injection units; in grave diabetes the quantity was materially lessened. Insulin administered in coma or precoma is not found in the urine. Following retention of carbohydrate, insulin-like substances are excreted in larger quantities; in the diabetic patient, however, the quantity of insulin is diminished for a few days. Also in the urine of the healthy dog insulin was found, but it disappears within a few days after the extirpation of the pancreas. Lublin of Breslau called attention to the mutual influence exerted on respiratory metabolism by insulin and synthalin, on the one hand, and by epinephrine and similar substances, on the other hand. The former facilitate the change of carbohydrates into fat; the latter make it more difficult or prevent it. Petrén of Lund gave his observations on sixty-eight instances of coma occurring in fifty-five diabetic patients during the past four years, who were treated with insulin. Three patients died from coma in the hospital; one because too little insulin was given him, and the two others because they refused insulin treatment; four died from coma at home and seven from other diseases. Injections of dextrose are not recommended, but rather a sensible diet with much fat, cream and vegetables (Petrén diet). Meyer-Bisch of Göttingen found in dogs and rabbits a blood sugar increasing action of the pancreatic juice that had been subjected to ultrafiltration, indicating the presence of an anti-insulin-like substance. In an alkaline animal there is a diminution of the blood sugar. Marx of Bonn succeeded through the ingestion of sugar in the healthy subject in producing changes in the water balance of the tissues, and in the diabetic patient, by the ingestion of water, he effected changes in the blood sugar content.

In connection with the roentgenologic diagnosis of the abdominal and thoracic organs, Wolf of Davos demonstrated the funnel shaped shadow in certain cases of tuberculosis. Götte demonstrated in subjects whose general clinical condition was but slightly disturbed extensive bronchopneumonic foci in the lung, which undergo rapid changes and are regarded as primary influenzal pneumonia. Paul Krause of Munster holds that iodized sesame oil as a contrast agent is indicated only in case operation is to be done, as injuries are apt to occur even with careful technic.

Pribram of Berlin demonstrated the method of roentgenologic examination of the duodenum with simultaneous injection of air and a small amount of the contrast agent. Gloor of Zurich emphasized that four symptoms were important for the early diagnosis of tuberculosis of the intestine: anemia, constipation, a negative Pirquet reaction and the presence of blood in the stool. Singer of Vienna recommended as cathartics quinine derivatives, which stimulate peristalsis of the large intestine. The application is intravenous, or in the form of suppositories or as an enema.

Marriages

Newell Walton Giles, Amherst, Mass., to Miss Emma Virginia Springer of Jackson Heights, Long Island, N. Y., May 23.

George Tryon Harding, III, Worthington, Ohio, to Miss Mary Virginia Woolley, of Atlanta, Ga., June 2.

Charles William Mayo, Rochester, Minn., to Miss Alyse Varney Plank of Philadelphia in June.

Walter Nathaniel Nelson, Bridgeport, Conn., to Miss Rachel M. Atwell of Durham, May 7.

Joseph G. Mayo, Rochester, Minn., to Miss Ruth Rakowsky of Joplin, Mo., June 11.

Konrad Frank to Miss Marie Fee, both of St. Louis, June 1.

Deaths

Virgil Pendleton Gibney ⊕ New York; Bellevue Hospital Medical College, New York, 1871; at one time clinical lecturer, clinical professor and professor of orthopedic surgery, Columbia University College of Physicians and Surgeons, New York; first president of the American Orthopedic Association; since 1922 surgeon emeritus of the Hospital for the Ruptured and Crippled; formerly on the staff of the St. John's Guild Hospital, New York Nursery and Child's Hospital and the Neurological Institute, New York, and the Bridgeport and St. Vincent's hospitals, Bridgeport, Conn ; author of "The Hip and Its Diseases"; aged 79; died, June 17, at his home in Bridgeport, Conn.

Bennett Franklin Davenport ⊕ Watertown, Mass.; Medical Department of Columbia College, New York, 1871; Harvard University Medical School, Boston, 1871; professor of chemistry, Massachusetts College of Pharmacy, 1879-1886; dairy inspector for the city of Boston, 1882-1885; chemist, Massachusetts State Board of Health, 1882-1892, and the state dairy bureau, 1892-1921; chairman of the Watertown health park and water boards; formerly coroner of Suffolk County; aged 82; died, June 3, at the Cambridge (Mass.) Hospital, of embolism following an operation for enlarged prostate.

Marie Charlotte Schaefer, Galveston, Texas; University of Texas School of Medicine, Galveston, 1900; member of the American Association of Anatomists; associate professor of histology and embryology at her alma mater; aged 52; died, May 27, at the John Sealy Hospital, of coronary thrombosis.

Clarence Wheeler Bassett ⊕ Sharon, Conn.; Medical Department of the University of the City of New York, 1882; health officer of Sharon; on the staff of the Sharon Hospital; aged 69; died, March 17, at St. Francis Hospital, Poughkeepsie, N. Y., of carcinoma of the colon.

Joseph Leo McGinley, Wilkes-Barre, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 46; died, May 18, of pulmonary tuberculosis.

Porter Thomas Fleming, Enterprise, Ala.; Louisville (Ky.) Medical College, 1894; member of the Medical Association of the State of Alabama; on the staff of the Coffee County Memorial Hospital; aged 59; died, March 28, of cerebral hemorrhage.

Jesse Wyllis Hassler ⊕ Belmar, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1892; member of the Florida Medical Association; aged 57; died, May 29, at Reading, Pa., following an operation for carcinoma of the pancreas.

Sylvester Edward Donovan ⊕ New Bedford, Mass.; Medical Department of the University of the City of New York, 1894; member of the New England Pediatric Society; on the staff of St. Luke's Hospital, where he died, May 30, of heart disease.

Loyal H. Tillotson, Painesville, Ohio; Homeopathic Hospital College, Cleveland, 1885; member of the Ohio State Medical Association; aged 67; died, March 27, at St. Petersburg, Fla., of progressive bulbar paralysis.

William Henry Axtell ⊕ Bellingham, Wash.; Medical College of Ohio, Cincinnati, 1891; member of the American Proctologic Society; served during the World War; aged 64; died, May 16, of angina pectoris.

James Noyes Lewis, Providence, R. I.; Medical Department of Columbia College, New York, 1874; member of the Rhode Island Medical Society; aged 77; died, May 28, at Ashaway, of heart disease.

Charles Denny Kimball, New York; University and Bellevue Hospital Medical College, New York, 1902; also a dentist; aged 52; died, May 25, at his home in New Rochelle, of pulmonary hemorrhage.

Ira Smith, Commerce, Okla.; University of Arkansas School of Medicine, Little Rock, 1907; member of the Oklahoma State Medical Association; aged 57; died, April 30, at a hospital in St. Louis.

William Bruce Macbean ⊕ Yonkers, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1903; aged 44; died suddenly, May 26, of angina pectoris and chronic nephritis.

John Howard Payne, Boston; Boston University School of Medicine, 1879; emeritus professor of ophthalmology at his alma mater; aged 72; died, May 29, of heart disease.

Newman T. B. Nobles, Cleveland Heights, Ohio; Cleveland University of Medicine and Surgery, 1896; aged 53; died, May 22, of embolism, following an operation on the gallbladder.

Charles Cincinnatus Henry, Brooklyn; Long Island College Hospital, Brooklyn, 1883; aged 78; died suddenly, May 16, at Baltimore, of skull fracture received in an accident.

William W. Baker, Washington, D. C.; Howard University School of Medicine, Washington, 1885; aged 79; died, May 16, at the Sibley Hospital, of injuries received in an automobile accident.

Thomas M. McIlvaine, Peoria, Ill.; Rush Medical College, Chicago, 1881; for many years a member of the school board; aged 73; died, May 17, at the Proctor Hospital, of pneumonia.

Walter Edwin Tiffin, Detroit; Detroit College of Medicine and Surgery, 1894; member of the Michigan State Medical Association; aged 60; died, May 23, of cardiorenal disease.

John J. McGlade ⊕ New York; Cornell University Medical College, New York, 1905; aged 44; was drowned, May 22, in the Peconic Bay, following an explosion on his launch.

Percy Lott De Nyse ⊕ Richmond Hill, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1909; aged 44; died, May 20, of heart disease.

Hubert E. Zilisch ⊕ Milwaukee; Marquette University School of Medicine, Milwaukee, 1923; aged 38; died, February 2, at St. Mary's Hospital, of nephritis.

Harold Bruce Boring ⊕ Denver; Jefferson Medical College of Philadelphia, 1912; aged 40; died, May 13, at St. Luke's Hospital, of cerebral hemorrhage.

Rosamond Louise Cox, San Francisco; University of California Medical School, San Francisco, 1888; aged 70; died, June 5, of cerebral hemorrhage.

Charles B. Lenox, Ashland City, Tenn.; Vanderbilt University School of Medicine, Nashville, 1893; aged 60; died, May 18, of chronic nephritis.

Albion King Parris Harvey, Livermore Falls, Maine; Chicago Homeopathic Medical College, 1888; aged 72; died, May 26, of heart disease.

John Stonewall Dunn, Brooklyn; Memphis (Tenn.) Hospital Medical College, 1883; aged 65; died, May 23, of bronchopneumonia.

August Horn ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1888; aged 58; died suddenly, May 31, of angina pectoris.

Frederic F. Seville ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1895; aged 60; died, June 4, of lobar pneumonia.

David Hall Courtney, Morgantown, W. Va.; Jefferson Medical College of Philadelphia, 1886; aged 67; died, May 27, of heart disease.

John Bunyan Herbert, Monmouth, Ill.; Hahnemann Medical College and Hospital, Chicago, 1872; aged 74; died, May 19, of myocarditis.

Thomas Darling, Gresham, Ore.; Detroit College of Medicine and Surgery, 1889; aged 77; died, May 12, of valvular heart disease.

Clarence E. Monroe, Toledo, Ohio; Starling Medical College, Columbus, 1888; aged 71; died, May 15, of cerebral hemorrhage.

Charles Edwin Barnes, Omaha; College of Physicians and Surgeons, Chicago, 1903; aged 46; died, May 20, of diabetes mellitus.

Peter B. Dick, Kennard, Ind.; Eclectic Medical Institute, Cincinnati, 1874; aged 89; died, May 18, following a long illness.

J. E. Mumford, Pleasant Hill, La.; Louisville (Ky.) Medical College, 1875; aged 74; died, May 17, of angina pectoris.

Samuel P. Swearingen, Pasadena, Calif.; Columbus (Ohio) Medical College, 1883; aged 74; died, May 12, of influenza.

Casper L. Bacon, Muncie, Ind.; Cleveland Medical College, 1896; aged 73; died, May 13, of myocarditis.

CORRECTION

Dr. Maurice Rosenberg Is Not Dead.—Based on information from the superintendent of the hospital in which he was reported to have died, an erroneous notice of the death of Dr. Maurice Rosenberg was published in The Journal, March 26. Dr. Rosenberg writes that he is very much alive, hale and hearty, and not a victim of diabetes, of which he is reported to have died.

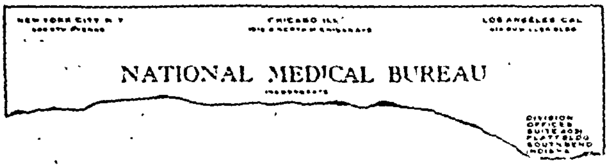
The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

NATIONAL MEDICAL BUREAU, INC.

Physicians are being circularized by a concern having the somewhat imposing name, National Medical Bureau, Inc. The letterhead of this concern carries with it the idea that it is a nation-wide organization having offices in New York City, Chicago and Los Angeles, with a "Division Office" at South Bend, Indiana.

The circular letter which the National Medical Bureau, Inc., sends to a physician states that it is about to appoint a physician in his locality to care for its members. It explains that the appointee would receive "50 per cent of the monthly membership fees in payment for his services," and in addition, "all of the regular revenue he normally derives from his medicines, drugs, medical supplies, and surgical operations." As a further inducement to apply for the appointment, the physician is told that, if selected, he was "automatically made the family physician in more than 500 homes of the city," whereby he could quickly build a practice that normally would take from ten to twenty years. The circular letter stated, further, that the doctor's "monthly checks average $250."



NEW YORK CITY N Y

CHICAGO ILL

LOS ANGELES CAL

NATIONAL MEDICAL BUREAU

DIVISION
OFFICES

These statements, if they mean anything, mean that the physician who signs up with the National Medical Bureau practically agrees to take care of 500 families for $250 a month, or at the rate of 50 cents a month ($6 a year) per family. Doubtless the medical service that such families would get would be in keeping with the amount paid the physician.

In order to qualify for the post of treating families at 50 cents a month, the National Medical Bureau outlines the requirements for appointment. These include:

1. Regularly kept office hours.
2. Maintaining neat, easily accessible offices.
3. The necessary instruments and equipment for surgical work.
4. The assurance that the physician would not charge excessive fees for services not covered by the membership.

As a further inducement, the physician is told that the "formal" mention of his name by the National Medical Bureau is a method of "indirect advertising" that "has a tremendous value."

Because the medical profession has been circularized, a letter was written to the National Medical Bureau at its Chicago address, asking certain pertinent questions, answers to which would permit inquiries from the medical profession to be answered intelligently. Specifically it was asked: Who are the incorporators of the *National Medical Bureau, Inc.?* Who are the officers? What is the character of the service that the National Medical Bureau, Inc., has to sell?

The letter, while sent to the Chicago office, was answered from South Bend and signed "W. Donald Dunkle, Division Director." Mr. Dunkle stated that a Mr. A. M. Nadel, who was out of the city, handled all the correspondence and that on his return, Mr. Nadel would be glad to answer any and all questions. A week later, a letter came from South Bend, signed "A M. Nadel, Division Director." Mr. Nadel, instead of answering "any and all questions," ignored the request for information regarding the incorporators and stated that the personnel of the board of directors had not been settled, all business being conducted by him.

Mr. Nadel was again written to and told that his letter threw but little light on a subject that was of peculiar interest to the medical profession. He was again requested to give the names of the incorporators, and attention was also called to the fact that, while the stationery of the National Medical Bureau gives the impression that the concern has offices in New York City, Chicago and Los Angeles, as well as South Bend, Indiana, all business seems to be done from South Bend. Mr. Nadel was asked for the names of the representatives in New York City, Chicago and Los Angeles, and also for the names of the individuals behind the National Medical Bureau.

After waiting another week, Mr. Nadel replied that the names of the incorporators were "of little or no importance" to the medical profession, and that the National Medical Bureau had not "seen fit to divulge" any of what he described as its "confidential information." He stated, further, that the personnel of the board of directors was still not settled, and that while they had New York City, Chicago and Los Angeles addresses, their entire activity was being conducted from South Bend, Indiana.

A letter was addressed to the Secretary of State of Indiana, stating that the National Medical Bureau, Inc., was doing business at South Bend and asking for the names of the incorporators. A reply was received from the Department of State declaring that the corporation division had no record of the National Medical Bureau, Inc., either as a domestic corporation which had filed articles of incorporation in Indiana, or as a corporation from some other state admitted to do business in Indiana. This may explain Mr. Nadel's airy dismissal of The Journal's request for information regarding the incorporators as a matter "of little or no importance."

Correspondence

A TEST PROCEDURE FOR THE EASY DIAGNOSIS OF EPIGASTRIC HERNIA

To the Editor:—Epigastric hernia is more common than the meager references to it would lead one to suppose. The reason is failure in diagnosis; for unless one is particularly on the lookout for it, one can easily miss it and attribute the symptoms to something totally different. Not every epigastric hernia will necessarily produce symptoms, but a small one may cause a wide variety simulating the condition set forth by Friedenwald and Morrison (The Journal, Oct. 30, 1926, p. 1466).

During the last three years I have seen about a score of such cases. The diagnosis has been made in almost every case by a certain procedure of palpation and, if indicated, confirmed by laboratory and roentgen-ray tests, which, of course, were negative. A clue to the condition may often be obtained from the history, especially when the symptoms are associated with pain which has no relation to food ingestion. The onset of an acute attack may be sudden, and often starts with some bending or twisting movement of the body. The character of the pain is frequently described as dragging—as if the "spine were being pulled forward into the stomach"—making it difficult for the patient to assume the upright posture in comfort. The severity of the attack may be anything from the agony of a gallstone colic to a dull aching pain. Associated with this there may be nausea and vomiting, but there is always a tenderness in the region of the hernia. Careful palpation, however. reveals the tenderness to be more superficial than it would be in any pathologic gastric or gallbladder condition, deep pressure being no more uncomfortable than superficial.

The diagnostic procedure which is invaluable to a correct diagnosis consists in causing a divarication of the abdominal rectus muscles with the patient supine, through the strain of lifting the head and shoulders off the table. With the abdominal wall relaxed, it is a matter of extreme delicacy to palpate adequately a small protrusion or hernia in the linea alba or semilunares, and as this relaxation is the usual status aimed at in any abdominal physical examination, it accounts for the frequency with which this condition is missed. When the abdominal wall is put on a strain, there will usually be seen in the average subject a shallow sulcus between the two rectus muscles, and if the finger is run down this sulcus the floor may readily be palpated for any small protrusions or depressions. When the patient is caused to cough, an impulse may or may not be elicited at one of these points. In some cases, however, there is a definite weakness of the fascial union of the recti, and then these muscles will widely diverge; instead of a shallow sulcus there will appear quite a deep wide groove and in extreme cases an actual gaping, through which the abdominal contents will protrude, causing a regular bulging which can be palpated, caused to receive an impulse through coughing, and returned to the abdominal cavity by manipulation. Indeed, I saw one such case in which, by the ordinary method of abdominal examination with the walls relaxed, no clue was obtained as to the condition, but when the patient strained to lift himself from the table a large bulging immediately appeared between the widely gaping rectus muscles which could be seen across the room. The diagnosis was immediately obvious. Since then I have used this procedure in every abdominal examination and by this means have been able to make a diagnosis of many epigastric hernias which I feel sure I would never have otherwise suspected.

The average man in general practice has doubtless seen several patients with gastric symptoms of indeterminate origin, who have drifted around from physician to physician, have been dosed with bismuth subnitrate and sodium bicarbonate, dieted and often hospitalized, but still have not been "cured." At last, through sheer lack of a better diagnosis, they are dubbed neurasthenics, and automatically any real interest in the case ceases. It is in precisely this class of unfortunates that the possibility of a small epigastric hernia should be considered, and I feel sure that a certain percentage will yield a positive diagnosis if submitted to the diagnostic procedure mentioned. Incidentally, ice to the epigastrium will usually relieve the pain of an acute attack.

Horace F. W. Warden, M.R.C.S., and L.R.C.P. (Eng.), Detroit.

POSSIBLE ARACHNIDISM

To the Editor:—The case reported by Dr. George L. Carrington (The Journal, April 30, p. 1395) as "Bilateral Diaphragmatic Pleurisy Simulating Perforated Gastric Ulcer" appears so typical of arachnidism that this diagnosis has been made independently by a number of physicians. Comparison with the description of arachnidism (The Journal, June 19, 1926, p. 1894) leaves little doubt as to the identity of the condition.

The history of a spider bite in a toilet followed in less than two hours by severe pains in the back and epigastrium, rapidly increasing in severity to the point of writhing and groaning from the intensity of the pain, with a feeling of impending death, vomiting, a rigid, boardlike abdomen, but without localized tenderness or point pain, a leukocytosis developing after several hours, a trace of albumin in the urine, and no response to large doses of morphine and codeine, occurring in a district like North Carolina (or any of our Southern states) where *Latrodectus mactans* is common, leaves little lacking for a diagnosis of spider bite poisoning.

Even the laparotomy with negative results may be considered part of the picture of arachnidism, as such operations have been performed in quite a number of cases which were later shown to have been instances of arachnidism.

The first recorded case of arachnidism in the United States was described by Hopton (*New York M. J.* **2**:297, 1829) nearly a hundred years ago, from the same state, North Carolina, and the first recorded death ascribed to spider bite poisoning was described by Dick in a letter in *Insect Life* (**1**:204 [Jan.] 1889) from the same neighborhood.

Emil Bogen, M.D., Cincinnati.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THALLIUM ACETATE AS A DEPILATORY

To the Editor:—Do you think that 8 grains of thallium acetate to an ounce of cold cream, containing some zinc oxide, rubbed on the skin to destroy hair would be absorbed by the skin enough to cause falling of the hair on the head or elsewhere? Do you know of anything except electricity that will permanently destroy hair? Please omit name.

M.D.

Answer.—In all probability, thallium acetate in an ointment will not cause falling of the hair when applied locally. If it will do so, the internal use of the drug can be avoided. There are other methods of destroying hair beside electrolysis, but *no other that is safe.*

"APOCACTIN" AND "PASCONIA" MERRELL

To the Editor:—I have received a letter from the William S. Merrell Company suggesting that I consult the firm's catalogue for "the particular kind of remedial agents for the different pathologic conditions met in daily practice." As an illustration of the helpful (?) advice that may be had from a perusal of the catalogue, three products are mentioned: "Apocactin," "a combination of drugs you don't often encounter"; "an efficient, nontoxic coagulant, Fibrogen"; and "Pasconia, a sedative and stabilizer in the erratic action of the 'nervous heart.'" I am not interested in the coagulant for the reason that it has not been admitted to New and Nonofficial Remedies along with similar preparations made by other firms. I am not much interested in "Apocactin" and "Pasconia" either, for reference to the catalogue shows that they belong to the genus "shotgun proprietary specialty" whose very complexity is sufficient to condemn them. However, I have become curious about the drugs that are said to be contained in them. They are not included in Useful Drugs or even in the pharmacopeia. Will you tell me something about them? Are they new drugs which have been recently discovered? According to the catalogue, "Each 10 minims [of Apocactin] . . . . represents F. E. Crataegus 2½ mins., F. E. Cactus 1 min., F. E. Apocynum 1-5 min., F. E. Avena Sativa 2 mins., F. E. Collinsonia 2 mins." For Pasconia, the following statement of composition is offered: "Each fluidounce represents: Passiflora Incarnata, green drug, 120 gr.; Avena Sativa 120 gr.; Collinsonia, green drug, 24 gr. In a suitable cordial."

H. T. P., M.D., Chicago.

Answer.—The drugs that make up "Apocactin" and "Pasconia" are not to be found either in Useful Drugs or in the United States Pharmacopeia. Some are not even included in the National Formulary, which aims to include preparations of drugs which are supposed to have any usefulness at all. All belong to that larger and ever growing collection of drugs that have been discarded because they were found to be inert or inferior to other drugs having the same action.

The following is the estimate of the Council on Pharmacy and Chemistry as given in the Epitome of the U. S. Pharmacopeia and National Formulary for those drug constituents of "Apocactin" and "Pasconia" which are included in the National Formulary: Passiflora (passion flower) "Exploited by manufacturers of proprietary medicines for the treatment of insomnia, but probably inert." Avena Sativa (oat) "A constituent of certain nostrums; has no place in the materia medica." Apocynum (Canadian hemp) "Cardiac tonic of digitalis group; unreliable as to rate of absorption."

Those drugs contained in the proprietaries but not even described in the National Formulary are Collinsonia and Crataegus. Collinsonia canadensis (stone root) was included in a report of the Council on Pharmacy and Chemistry, "Some Unimportant Drugs" (Reports Council Pharmacy and Chemistry, 1912, p. 36) which states that for some time the drug had a reputation as an antispasmodic, astringent and diuretic, and that although there appears to be some evidence that this drug possesses some activity, this seems to be such as is better exhibited by other drugs. Crataegus Oxycantha (hawthorn) was proposed for use in cardiac disease many years ago, but has not gained a place in our materia medica.

MILK AND RICKETS — INFANT'S MILK REQUIREMENT

To the Editor:—1. Several well known German pediatricians state that too much milk, whether breast or bottle, if given to an infant for a considerable length of time, plays an important part in the etiology of rickets. What is the explanation? 2. Considerable discussion has been given by many European pediatricians to the amount of whole milk that the healthy infant requires daily. Many state that no infant in the first year requires more than 500 cc. of milk daily, reducing the milk even still further in the second year to 400 cc. and later to 200 cc. daily in normal infants. Kindly explain the advantages derived from these reductions, and state whether such reductions are advisable in healthy infants.

Samuel Grossman, M.D., Taunton, Mass.

Answer.—1. If an infant is kept on breast milk alone for too long a time it commonly develops rickets, probably not so much because of the milk as because of the absence of other foods. That too much breast milk in itself ever causes rickets is certainly doubtful. That prolonged feeding of an excessive amount of cow's milk, especially without an adequate addition of carbohydrates, produces serious disturbances in the infant's mineral metabolism is well known (Czerny's Milchnährschaden). Rickets is a common manifestation of this disturbance. In the production of rickets one must, however, always reckon with the other equally important fundamental factor: the absence of a sufficient amount of ultraviolet rays.

2. There is so much authoritative difference of opinion concerning the optimal amount of milk for the normal infant that this question cannot be answered dogmatically. There is no doubt that many infants, notably older ones, will do better if given less than the conventional quart of milk a day, especially if by so doing they will take other foods with greater readiness. The view that the amount should as a routine be reduced to 500 cc. a day during the first year, and even to 400 and 200 cc. during the second and third years, has only a limited adherence among "European pediatricians" and practically none in this country, except in the isolated case in which there is a resulting lessened appetite for other foods, or an intolerance for milk. The effect on the fecal flora of foods, such as carbohydrates, as compared with that of milk, is probably an important factor. The more recent tendency of the vitaminists and their lay followers to push milk to "a quart or more a day" takes cognizance of only one factor, which is, moreover, adequately represented in other foods, at the expense of the harm that may come from giving too much milk in the individual case. It is probably still a safe rule to offer a child, as a routine, as much of a quart of milk a day as he will take, unless there is some obvious reason for cutting down the amount.

TREATMENT OF HERPES

To the Editor:—I have under my care an unmarried woman, aged 29, who is suffering from recurring attacks of herpes labialis. The lesions have recurred at intervals of about six weeks for the last four or five years, and have occurred in one spot on the upper lip. There are no residuals noted between attacks. Many different local treatments have been tried, but these have been only partially successful, the lesion apparently running its course in spite of treatment. Her general health is good, and foci of infection have been searched for but not found. Would you kindly comment on this case and suggest local and general treatment?

John W. Visher, M.D., Waukesha, Wis.

Answer.—In patients who are subject to herpes almost any sort of a systemic upset is apt to produce it; also innumerable kinds of external irritation, such as driving in the wind, exposure to sunlight, or local irritants to the lips. Thus, in the prevention of herpes, all these things need to be guarded against as far as possible. Often the lips can be made less sensitive by the use of astringent applications. A good application of this sort is zinc sulphate, from 0.25 to 1 Gm. to 120 cc. of water. Begin with the weaker solution; sponge the lips with this once a day. If it does not produce irritation, increase the strength gradually to the point at which it begins to cause slight irritation; then go back to a solution that is just short of producing irritation. Also greasing of the lips with cold cream or with cold cream containing 4 Gm. of zinc oxide and 4 Gm. of calamine to 30 Gm. keeps them in good condition and tends to prevent the trouble.

College of Medical Evangelists	(1921)	California
University of Maryland School of Medicine	(1917)	Maryland
Medical College of Virginia	(1924)	W. Virginia

Book Notices

History of Prostitution Among All the Peoples of the World, From the Most Remote Antiquity to the Present Day. Three volumes. By Paul LaCroix, Member of Many Academies and Learned Societies French and Foreign. Translated from the original French by Samuel Putnam. Cloth. Price, $36 per set. Pp. 1749. Chicago: Pascal Covici, 1926.

The author, who was a French journalist, reveals in three large volumes, translated by an American journalist, his conception of the history of prostitution from the earliest times to the end of the seventeenth century. The early history is taken from allusions in the classical writings of Greece and Rome, the latter discussions based as much on romance as on history of the middle ages. Like many other French writers, LaCroix is passionate and has a flair for the romantic. Of particular interest to the physician is that section of the second volume which deals with the introduction of syphilis into Europe and its spread through prostitution to all the peoples of the world. LaCroix chooses to accept the doctrine that syphilis was identical with the plagues of biblical times, perhaps something in the nature of a new exacerbation. He discounts completely the conception that it may have been introduced into Europe by the returning sailors of the Columbian voyages. The volumes are beautifully printed in a limited edition, and constitute a reference work as well as the means of passing many hours in interesting reading. They are, however, suited only to those whose work takes them especially in these fields, and who will be able to view the pronouncements in proper perspective.

Symptom Diagnosis, Regional and General. By Wilfred M. Barton, A.M., M.D., F.A.C.P., Associate Professor of Medicine, Medical Department of Georgetown University, and Wallace M. Yater, A.B., M.D., Fellow in Medicine, Mayo Foundation, Rochester. Cloth. Price, $10. Pp. 851. New York: D. Appleton & Company, 1927.

This volume has been prepared by the authors as an immediate aid to the puzzled physician in arriving at a diagnosis of disease. Indeed, the suggestion is made in the preface that the book is to be used as a quick reference while the patient is being prepared for examination or while he is dressing after the examination. It is arranged with special reference to the regions of the body and to the symptoms associated with those regions. For example, the single symptom "headache" occupies the first twelve pages of the book; it is discussed with relation to the portion of the head concerned and the possible disease conditions that might produce such a headache. The work is not readable in the ordinary sense of that term; it is strictly a work of reference, largely in outline form. It is not so much a work of diagnosis as of differential diagnosis, serving largely to suggest to the user the things that he may have overlooked.

Traité de physiologie normale et pathologique. Publié sous la direction G.-H. Roger, professeur de physiologie à la Faculté de médecine de Paris, et Léon Binet, professeur agrégé de physiologie à la Faculté de médecine de Paris. Tome XI. Reproduction et croissance. Par. M. M. Léon Binet, H. Busquet, et autres. Cloth. Price, 65 francs. Pp. 496, with illustrations. Paris: Masson & Cie, 1927.

This is a composite production containing chapters on: histogenesis of the sex cells by Champy; sex physiology of the male by Busquet; sex physiology of the female by Vignes; secondary sex characters by Pezard; physiology of pregnancy by Vignes; physiology of the new-born by Binet; physiology of lactation by Porcher; histology of growth by Champy; physiology of growth by Champy and Binet; heredity by Binet, and teratology by Rabaud. As in similar monographs by several authors, the chapters have unequal value; the monograph as a whole is reliable, helpful and fairly comprehensive. The chapters by Dr. Vignes are particularly excellent. Dr. Pezard, who writes on the secondary sex characters, has done much experimental work on the physiology of sex and sex characters, particularly among birds. It is therefore surprising to find that on many points this chapter is not down to date. Dr. Pezard seems unfamiliar with the recent important work in this field by Drs. Moore and Oslund in this country. The other chapters contain valuable references to the world literature on the specific points under discussion. This is volume XI of a large work on normal and pathologic physiology under the editorship of Drs. Rogers and Binet of the Paris Faculty of Medicine. The completed series will constitute a valuable work for reference.

Black's Medical Cyclopedia. By John D. Comrie, M.A., B.Sc., M.D., Lecturer on Practice of Medicine in the School of the Royal College at Edinburgh. Eighth edition. Cloth. Price, $6. Pp. 998, with 507 illustrations. New York: Macmillan Company, 1926.

This volume, now in its eighth edition, has sold more than 60,000 copies. It is an a-b-c guide to medical knowledge, a sort of first aid to the physician who needs ready reference. While it is not a complete work in the sense that some of the larger reference handbooks are, it is much more than a dictionary.

Social Adjustment. By Robert Cloutman Dexter, Ph.D., Professor of Social and Political Science, Skidmore College. Cloth. Price, $3.50. Pp. 424. New York: Alfred A. Knopf, 1927.

This volume is an attempt to answer the greatest question of all times; namely, why people go wrong. The answer, as given in the first chapter, is apparently that most of us have little knowledge as to how we should conduct ourselves toward our neighbors, or of the importance of the lives of others in controlling our own. Poverty, it is clear, is one of the greatest causes of dependency and is the result not only of economic factors but also of political, social, religious and similar causes. Dr. Dexter is convinced that private relief agencies have established a system by which public relief agencies will in the future take care of the indigent and the dependent. Much of the volume is devoted to the newer efforts to give the child a proper opportunity to develop along the most suitable lines. A special chapter deals with the problems of old age; others with disease, particularly such as can be controlled by the social scheme. The book is beautifully printed. It is written in a straightforward, narrative style, and is, among all the sociological works of modern times, one of the most readable. An extensive bibliography provides reference to periodic literature, to national organizations in the field of public welfare, and to similar topics.

Manual of Clinical and Laboratory Technic. By Hiram B. Weiss, A.B., M.D., Assistant Professor of Medicine, College of Medicine, University of Cincinnati, and Raphael Isaacs, A.M., M.D., Instructor in Medicine, Harvard Medical School. Third edition. Cloth. Price, $1.25. Pp. 78, with illustrations. Cincinnati: Cincinnati General Hospital, 1927.

This is another of the many guides prepared for the hospital intern in conducting his work. It begins with an outline for the taking of an ordinary history, and follows with the special history required for neurologic examination. The succeeding sections provide the technics for the laboratory tests associated with body fluids and for functional tests related to various organs. There are also directions for paracentesis, intravenous therapy, skin tests, blood grouping and similar topics, a table of normals in blood chemistry, and of abbreviations useful in recording observations. A section entitled "Therapeutic Measures" records briefly some specimen diets, and other tabulations provide material for estimation of calories and other factors associated with food. The material is practical and well suited to the purpose for which it was prepared.

Food, Nutrition and Health. By E. V. McCollum, Ph.D., Sc.D., Professor of Chemical Hygiene, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, and Nina Simmonds, Sc.D. (Hygiene), Associate Professor of Chemical Hygiene, School of Hygiene and Public Health, Johns Hopkins University, Baltimore. Cloth. Price, $1.50. Pp. 143. Baltimore, 1925.

This booklet, written primarily for the general public, gives in simple form the fundamental facts that every person ought to have relative to the human diet. It tells what is actually known concerning the vitamins A to D; it points out the importance of mineral salts and of proteins, carbohydrates and fats. It discusses foods of vegetable and animal origin, and the general question of hygiene of the digestive tract. Several chapters concern scientific reduction of weight, and the book concludes with a system of diet for promoting health, accompanied by numerous suggestive dietaries. The language throughout is simple, the discussions informative and interesting, making the book one that should appeal to every reader, lay or medical. Indeed, one might wish that all physicians were fully conversant with the points covered by this volume.

Die Zuckerkrankheit und ihre Behandlung. Von Dr. C. von Noorden, Geh. Medizinalrat-Professor an der Universitat Frankfurt a. M., und Dr. Isaac, Professor an der Universität Frankfurt a. M. Eighth edition. Paper. Price, 46.50 marks. Pp. 627, with 30 illustrations. Berlin: Julius Springer, 1927.

Ever since the first "von Noorden" appeared, successive editions have marked the progress of diabetes mellitus. No better evidence of the extent of this progress can be obtained than by a comparison of the 438 pages of the sixth edition of 1912 with the 627 pages of the present volume. Although the general form of the two volumes is the same, the division of discussions shows the effect of the discovery of insulin on all phases of the subject. The theory of the disease, the pathology, the chemistry are interwoven with details of treatment into an encyclopedic whole too massive to grasp except on repeated readings. To review an encyclopedia is a difficult task; one knows that the von Noorden first volume was a real contribution to diabetes; and one notes that the present edition has carried the subject well up to the last minute. The references to the literature are particularly gratifying, since they show a keen appreciation of the real contributions made by investigations in Canada and the United States to the study of this fascinating disease.

Immunity in Syphilis. By Alan M. Chesney, Johns Hopkins Medical School. Cloth. Price, $2.50. Pp. 85. Baltimore: Williams & Wilkins Company, 1927.

The very title of this monograph brings to mind classic controversy. Is the rarity of a second attack of syphilis due to acquired immunity or to incomplete cure of the original infection? What is the nature of the so-called antibodies in syphilis? These and other questions relating to syphilis in man as well as in monkeys and rabbits are discussed in a critical and readable manner. The author is well known by his extensive experiments in immunity in syphilis carried out in collaboration with associates at the Johns Hopkins Medical School, and he is especially fitted to discuss this subject. The volume combines a brief summary of the old views and an extended summary of modern opinion, based on recent investigations, and should be of great interest to students of syphilology.

Anatomical Texts of the Earlier Middle Ages. A Study in the Transmission of Culture with a Revised Latin Text of Anatomia Cophonis and Translations of Four Texts. By George W. Corner, M D., Professor of Anatomy in the University of Rochester. Paper. Pp. 112. Washington: Carnegie Institution of Washington, 1927.

Dr. George W. Corner has prepared this work with the guidance of Dr. and Mrs. Charles Singer, M. Wickersheimer, and others recognized as leaders in the field of medical history. He carries the study of anatomy from the period of the school of Salernum through the twelfth and thirteenth centuries, quoting repeatedly from many little known texts and citing numerous examples of the manner in which modern anatomy became a science. A large portion of the book is devoted to the anatomies of Nicolai and Ricardi Anglici.

Atlas of the History of Medicine—Anatomy. By Dr. J. G. de Lint, Lecturer on the History of Medicine at the University at Leiden. With a foreword by Charles Singer. Cloth. Price, $6. Pp. 96, with 199 illustrations. New York: Paul B. Hoeber, 1926.

In this work the author provides a collection of a series of descriptive paintings and portraits illustrating the history of anatomy from the earliest times to the nineteenth century. Accompanying each of the illustrations is a brief text, including a biographic note of the individual concerned, as well as the material illustrated. The book is in every sense a contribution to the subject of illustrations as related to the growth of medical science.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits. Books listed in this department are not available for lending. Any information concerning them will be supplied on request.

Fortschritte der naturwissenschaftlichen Forschung. Herausgegeben von Prof. Dr. Emil Abderhalden. Band XII. Heft 4. Die Wirkungsweise abgestufter Keimdrüsenschädigung. Eine experimentelle Studie zur Frage der endokrinen Sexualfunktion. Von med. Dr. Heinrich Viktor Klein. Paper. Price, 12 marks. Pp. 378, with 6 illustrations. Berlin: Urban & Schwarzenberg, 1927.

Experimental studies tending to disprove most of the Steinach claims.

Diseases of the Digestive Organs with Special Reference to Their Diagnosis and Treatment. By Charles D. Aaron, Sc.D., M.D., F.A.C.P., Professor of Gastro-Enterology and Dietetics in the Detroit College of Medicine and Surgery. Fourth edition. Cloth. Price, $11. Pp. 927, with 257 illustrations. Philadelphia: Lea & Febiger, 1927.

New edition with special revision of sections on liver, on roentgen ray and many other topics.

Practical Gastroscopy. By Jean Rachet, M.D., Assistant to the Hôpital St. Antoine, Paris. Authorized translation by Fred F. Imianitoff, D.S.C., B.A., M.R.C.S., Assistant to the Gynecological Research Department, Institute of Anatomy, Brussels. Cloth. Price, $5.50. Pp. 148, with 60 illustrations. New York: William Wood & Company, 1927.

Well illustrated monograph giving special technic and values in diagnosis.

A Manual of Gynecology. By John Osborn Polak, M.Sc., M.D., F.A.C.S., Professor of Obstetrics and Gynecology, Long Island College Hospital. Third edition. Cloth. Price, $5. Pp. 402, with 157 illustrations. Philadelphia: Lea & Febiger, 1927.

New edition of practical manual with references to newer literature.

Urinary Surgery. A Handbook for the General Practitioner. By William Knox Irwin, M.D., F.R.C.S.E., Surgeon to Out-Patients, St. Paul's for Genito-Urinary Diseases, London. Second edition. Cloth. Price, $4. Pp. 271. New York: William Wood & Company, 1927.

Outline of surgical technic in urology without illustrations.

Adapted Group Gymnastics. By Lillian Curtis Drew, Director of Department of Corrective Gymnastics, Central Branch, Y. W. C. A., New York City. Cloth. Price, $1.75. Pp. 150, with illustrations. Philadelphia: Lea & Febiger, 1927.

Well presented outline for teachers of gymnastics.

Dudley Allen Sargent: An Autobiography. Edited by Ledyard W. Sargent. With an introduction by R. Tait McKenzie, M.D. Cloth. Price, $2. Pp. 221, with portrait. Philadelphia: Lea & Febiger, 1927.

Personal record of an American leader in physical education.

La vacunación contra tifoidea: Conferencia pronunciada en los salones de la junta nacional de sanidad y beneficencia. Por. Dr. J. A. Lopez del Valle. Paper. Pp. 41. Havana, 1926.

Exposição de motivos sobre o problema da prophylaxia da lepra no estado de São-Paulo. Por G. H. de Paula Souza. Paper. Pp. 115, with illustrations. São Paulo, 1926.

Organisation et hygiène sociales: Essai d'hominiculture. Par Jules Amar, professeur de physiologie du travail Paper. Pp. 692, with illustrations. Paris: Dunod, 1927.

Report on the Health of the Army for the Year 1925. Volume LXI. Paper. Price, 3s. 6d. net. Pp. 152. London: His Majesty's Stationery Office, 1927.

Inyecciones subcutaneas de oxigeno. Por el Dr. Adan Cuadra, profesor de pediatría de la escuela de medicina de Granada. Paper. Pp. 45. Granada, 1927.

I tumori della ghiandola carotidea. Per Dott. G. Aperlo e Dott. F. Rossi. Paper. Pp. 115, with 15 illustrations. Milan: Francesco Vallardi, 1927.

The American Medical Association of Vienna. Paper. Pp. 248. Vienna, 1927.

Glycogène, adrénaline et insuline. Par M. Jacot. Paper. Price, 35 fr. Pp. 209. Paris: Masson & Cie, 1926.

PRESS COMMENT ON THE WASHINGTON SESSION

As was pointed out in The Journal a few weeks ago, the Washington Session aroused more important newspaper publicity than has any previous annual session of this organization. This resulted no doubt largely from the timeliness of the issues discussed and from the fact that the President of the United States addressed the opening meeting. Further factors were the relationships to the press established by the Association in recent years and the presence in Washington of representatives of most important American newspapers and news gathering organizations.

Editorial comment on the meeting and on the issues was striking and important. Indeed, editorials continue to appear daily in various parts of the country still referring to the Washington session. The physician has quite certainly not lost prestige but continues to have in greater measure than ever before the confidence of the public.

LIQUOR

Public confidence was most apparent in the reaction of the newspapers to the adoption by the House of Delegates of the suggestion "to draft a bill which shall include an amendment to the Volstead Act to remove the pint in ten days limit." As might be expected, there was nearly three times as much material dealing with this aspect of the work of the convention as with any other. The great majority of the newspapers, from all parts of the country, stood squarely behind the House of Delegates.

The New York *Evening World* of May 18 used no uncertain language:

> The action was taken in executive session and is said to have been by a unanimous vote. This is no more than these physicians should have done.
>
> It should have been done in the open, but it required some courage to do it at all in these days when pussyfooting and hypocrisy are common. There is so much of downright impertinence in politicians and Anti-Saloon League hirelings presuming to determine how a physician shall practice medicine and save human life that it is utterly indefensible.
>
> There are thousands of the best physicians in the country who believe that liquor is not only helpful in the treatment of some diseases but absolutely necessary to the saving of life in some others. These men have a sacred duty. To prohibit them from saving life through fanatic legislation is to commit murder. The murderer in such an instance is the Congress of the United States Even so, some physicians have boldly declared their intention to prescribe liquor when they deem it necessary, regardless of the law.

On the same date the New York *Herald-Tribune* was more restrained but none the less certain that

> The law, as it stands now, prohibits the medical man from giving his best services to his patient. Congress should give the doctor the chance to carry out the Hippocratic oath, which says: "I will follow that system of regimen which, according to my best judgment, I consider best for my patients and abstain from whatever is injurious."

As a means to do away with what its contemporaries plainly indicated as an abuse, the New York *American* suggested:

> The remedy is to ask Congress to reconsider. On this point the medical profession is justified in becoming active in politics as a unit. When so stirred it can prove that it is a power.

Philadelphia editors expressed views similar to those just quoted, while the Chicago *Tribune* of May 25 voiced the prevailing attitude of the Middle West:

> Law does not restrict the dosage of other medicine available for the practitioner and patient. It comes within the physician's judgment and discretion. This is peculiar law. Volstead and the doctor are supposed to go arm in arm to the patient, and if the doctor prescribes whisky the Volstead Act prescribes how much.
>
> This transparently follows the legal assumption that doctors would make an illegal use of the prescription and release large quantities of liquor for beverage purposes. The medical code of honor is a high one and it governs in most particulars the majority of practicing physicians, but there are prescriptions which satisfy an appetite for stimulants rather than provide medical requirements. The majority of doctors, scrupulous in their practice of medicine, find that their whole profession rests under the legal implication that they must have a dosage given by law, and they resent it, but it is a congenital part of a law which in essence is a denial of judgment and discretion. The Volstead Act assumes that the American people cannot be trusted with their own morals, health, deportment and conduct, being in this respect unique among the supposedly civilized people of the world. It is a part of that to assume that American doctors generally cannot be trusted to prescribe medicine if there is any chance of medicine being used as a beverage.

In the South, the famous old Louisville *Courier-Journal* of May 20 wrote:

> Only the physician is competent to judge whether and how much his patient needs whisky, and it is crass effrontery for Congress or the Anti-Saloon League to usurp his functions. Self-respecting physicians are justly resentful of this usurpation and they would manifest no proper appreciation of their own responsibility if they did not insist on their right and competence to practice their profession and did not rebel against the attempt of any legislative body to practice it for them.

Although other papers through the South were in general accord with the sentiments of the *Courier-Journal*, a note of pessimism was sounded by several of them. This temper was well summarized in these lines from the Lynchburg, Va., *Advance* of May 19:

> As stated, medical opinion is not unanimous upon the question of the value of liquor as a medicine. Congress might take either of the prevailing opinions, act upon it and not be illogical. The attempt to straddle is wrong. Either there should be no restrictions on physicians, as the American Medical Association asserts, or the use of liquor as medicine should be forbidden altogether in conformity with minority but highly intelligent medical opinion.
>
> It is not likely, however, that the law will be changed. Politics rather than logic will rule in the matter.

A closely related attitude to that of complete support of the House of Delegates was whole hearted condemnation of the efforts of the drys. "Mr. Wayne B. Wheeler," said the New York *World* of May 19,

> runs perfectly true to form in his ultimatum to the American Medical Association not to appeal to Congress to remove restrictions on the use of alcohol as medicine. In the first place, he knows more about medicine than the doctors, just as he knows more about ethics than the philosophers, more about human nature than the psychologists and more about the administration of justice than the courts; he is perfectly certain how alcohol should and should not be used to obtain "every therapeutic reaction."

Certain editors took a middle ground, and pointed out that in 1917 the medical profession declared alcohol to be valueless in therapeutics. "But," said the Newark, N. J., *News* of May 20,

> the referendum taken by the journal of the association in 1921, in which more than 31,000 pyhsicians, by 51 to 49 votes in each 100, declared liquor a medical agent of value, had already reversed that 1917 judgment. In the interim the influenza-pneumonia epidemics had shown that in some medical crises alcoholic stimulation of the sick is imperative, far beyond the Volstead Law's homeopathic dosage. In this latest action the doctors properly are not so much concerned with the question whether whisky is a disease specific as with their professional right to practice their calling according to their training and experience.
>
> That the doctors have blood in their eyes as to this business is made apparent by their simultaneous determination to demand control of patent medicines, which are largely alcohol. They make the point that these are illegal, under the law as it stands, wherever the spirit content is as much as one-half of one per cent. While legitimate medical practice is restricted to a driblet, the open door to this sort of flood is a fitting commentary upon the sanity of prohibition enforcement.

An occasional paper was not convinced that experience under the Volstead Law justified freedom in prescribing. The Milwaukee *Journal* of May 22 expressed some distrust:

> Congress has no business telling doctors what quantity of alcohol is sufficient for treatment. But, on the other hand, a doctor has no business prescribing alcohol to an obviously well person. And some doctors unquestionably have done just that.
>
> In some circles liquor scripts seem to have been considered more in the light of their equivalent in legal tender than in the light of their value in the treatment of disease. Men who "wanted to have a little something in the house in case of illness" have been accommodated. Doctors are doing less of this accommodation than formerly, it is understood. They have long since grown weary of the impositions of friends. But the powerful medical associations seemingly have done little to discourage this thing.
>
> The "pint-in-10-days" measure is an unwarranted interference with the conscientious physician who looks upon liquor as a real therapeutic agent. But one cannot be blind to the abuse which led to the writing of the prescription by Dr. Congress.

A corollary of this attitude was that expressed in the New York *Telegram* of May 20:

> The Volstead Act went too far when it sought to control the legitimate practice of medicine. So long as prohibition is the law of the land, however, there is reason in enough regulation to prevent charlatans from abusing their privileges as physicians and becoming in effect bootleggers.

The Wheeling, W. Va., *Register* of May 21, under the title "Doctors Shouldn't Misplace the Blame," distinguished between the authority of Congress and of the Supreme Court:

> To decree that a physician competent to be entrusted with care of the sick may not prescribe for a patient needing stimulation more than one pint of whisky in ten days is quite obviously a foolish use of the statutory power. But it is no part of the duty of the Supreme Court to save this nation from folly. Its function is to pass, not upon the wisdom but upon the constitutionality of laws.

The instances of qualified approval and partial disapproval were few. A slightly larger number were definitely against removal of the restriction. The papers represented in this body of unfavorable opinion include the Mishawaka, Ind., *Enterprise*, May 25; Statesville, N. C., *Landmark*, May 19; Owensburg, Ky., *Messenger*, May 19; Sterling, Ill., *Gazette*, June 1; Clarksville, Texas or Tenn., *Chronicle*, May 18; Bluffton, Ind., *Banner*, May 19. Five papers, from small communities in Indiana, Mississippi and Michigan (Union City, Ind., *Times*, May 26; Rushville, Ind., *Republican*, May 21; Madison, Ind., *Courier*, May 27; Hattiesburg, Miss., *American*, May 26; Battle Creek, Mich., *Enquirer News*, May 23) have apparently reprinted a syndicated article. Thus, the Peoria *Journal* of May 17 concluded its editorial with the two following paragraphs:

> The layman is under no delusion as to "prescription" whisky. He knows that the physician who "prescribes" it is merely using his legal authority to collect $3 for writing his name on a blank furnished by the government. The "patient" would take no greater chances if he paid his money directly to the druggist or to the messenger boy who makes delivery.
>
> If the American Medical Association hopes to denaturize the Volstead act of its hypocrisy, it is undertaking a herculean task. The real law enforcers are opposed to whisky for all purposes—beverage, medicinal and industrial. Opponents of the Volstead act, on the other hand, are fighting it on all grounds. In the meantime, "prescription" whisky, having been a fake from the beginning, can scarcely be raised in honor by an ancient and noble profession.

One wag, on the Nashville, Tenn., *Banner*, is not worried by the controversy. Perhaps the nearness of Appalachian fastnesses has kept him mellow. On May 20 he wrote:

> The members of the American Medical Association in Washington are said to have been considering the matter of liquor behind closed doors. Well, that's the general custom of the country, isn't it?

PRESIDENT COOLIDGE

Next to the liquor question, the press seized most eagerly on the convention address of President Coolidge. The mass of material taken from this address and selected for editorial comment was great; much of it, it seems, was obtained from syndicates. As a general summary, apparently independently written, the Trenton, N. J., *Gazette* of May 19 printed the following, under the title "Medical Values":

> A notable tribute to the physicians of the land was paid by President Coolidge in his address before the American Medical Association. Without giving expression to fulsome praise, the President called attention to the high ethical standards which maintain throughout the profession and which are contributing so markedly to the quest for social perfection.
>
> Here are a few of the professional qualities to which Mr. Coolidge pointed: Service, open-mindedness, heroism, cooperation, tolerance and progressiveness. And as for the altruism of medical men, he declared that they are uniformly willing to serve the interests of human welfare even when such action diminishes the income to be derived from their practice.
>
> The President's observations will commend themselves to thoughtful people everywhere. Members of the medical profession, owing to self-imposed restrictions, usually disdain the plaudits which their services to humanity merit. The general practitioner, as well as the laboratory expert, normally fails to receive the public acclaim which is his just due.
>
> And so, a pleasing element of equity is contained in these remarks of Mr. Coolidge. Indeed, here is a body of scientists which, as the President noted, may well make large contributions to world regeneration "physically, mentally and spiritually, when not force but reason will hold universal sway." In voicing this thought, the White House was speaking for America at large.

The Indianapolis *News* requoted the tributes paid by the President and concluded:

> We know of no other group of men who have deliberately set out to destroy the demand for their services. By preventing illness through public spirited work for sanitation and hygiene among all people they have reduced the scope of their practice. This is in keeping with their vows as men of science and ministers to the needs of the suffering without regard for their own personal welfare. The tribute paid to them and their calling by the President was well deserved. It is felt by every citizen, who has—or should have—a keen sense of obligation to the school which in recent years has added twenty years to his expectation of life.

A syndicated editorial appearing in many newspapers of the Middle West, including the Gary (Ind.) *Post-Tribune*, the Newcastle (Ind.) *Courier*, the Riverdale (Ill.) *Pointer*, and others, concluded:

> Thus the community owes a big debt to its physicians. There are several ways in which we can do something to pay it. Many doctors charge little to people of limited means and that generosity is no doubt abused. If a person can by any possible effort pay his doctor's bill he should certainly do so and work a little harder to avoid being the recipient of this form of charity.
>
> If one could look through the books of the average doctor he would find many accounts due from people who are perfectly able to pay, but fail to do so out of neglect and indifference.

The New York *Sun* emphasized the increasing span of life due to the work of medical science:

> How nobly the doctors have been changing the notions of humanity as to youth and age is shown by the simple fact that Moliere, who died at 51, thought that a man was getting well along in years at 30, an age at which most moderns think themselves rather young to marry.

Comparing the practice of medicine with that of law, to the disadvantage of the latter, the New York *Telegram*, after pointing out the increasing number of laws on the statute books, said:

> It would be much the same if young physicians got busy after graduation inventing new diseases or finding new germs, microbes and bacilli with which to infect the human race, so as to make more business and more money for physicians.
>
> If President Coolidge gets a chance to address the American Bar Association he might render a public service by inviting attention to the noble example set by the medical profession in their advocacy of prevention.

Newspapers everywhere endorsed all the kind sentiments relative to the medical profession expressed by the President, and the Flint (Mich.) *Journal* answered well for them:

> The medical men present knew every fact and every bit of statistics President Coolidge quoted, but this semi-official speech of appreciation, expressing the thanks of the nation for the services of its great army of physicians, must have been cheering to those who carry on the health work day by day, too often with small thanks for their effort.

MEDICAL ECONOMICS

Judging from space used by the newspapers, the public is next most deeply interested in the cost of sickness as presented by President Jackson. Again the syndicated article found favor. One of these entitled "Paying the Doctor," which appeared in several of the large papers in various parts of the country, is printed herewith:

> In this day of tonsils and adenoids, paying the doctor has become one of the greatest problems in the life of the average salaried man.
>
> The American Medical Association has recognized the burden that the wage earner has to bear and its president, Dr. Jabez North Jackson of Kansas City, has just issued an appeal for endowment of hospitals for what he calls the great middle class.
>
> Doctors have three kinds of patients: charity, very rich and those that pay their fees on the instalment plan.
>
> The charity patients receive medical attention free, it being considered humanitarian for the medical men to volunteer their services to public and charity institutions.
>
> The wealthy clients pay fees in keeping with their incomes, thus making up to the physician for the time and expense of caring for his free patients.
>
> Those that pay on the instalment plan are the wage earners, too proud to accept free medical attention, who go into debt and pinch themselves to meet the doctor's bills as well as the bills of the hospitals and the nurses.
>
> Being ill is a rich man's luxury or a poor man's paradise, but for the middle man it is a financial calamity.
>
> Hospital fees have become so great that only a rich man can afford to pay them. The poor man is protected because philanthropists have endowed institutions to provide him with the proper care and attention during illness.

While legitimate medical practice is restricted to a driblet, the open door to this sort of flood is a fitting commentary upon the sanity of prohibition enforcement.

An occasional paper was not convinced that experience under the Volstead Law justified freedom in prescribing. The Milwaukee *Journal* of May 22 expressed some distrust:

> Congress has no business telling doctors what quantity of alcohol is sufficient for treatment. But, on the other hand, a doctor has no business prescribing alcohol to an obviously well person. And some doctors unquestionably have done just that.
>
> In some circles liquor scripts seem to have been considered more in the light of their equivalent in legal tender than in the light of their value in the treatment of disease. Men who "wanted to have a little something in the house in case of illness" have been accommodated. Doctors are doing less of this accommodation than formerly, it is understood. They have long since grown weary of the impositions of friends. But the powerful medical associations seemingly have done little to discourage this thing.
>
> The "pint-in-10-days" measure is an unwarranted interference with the conscientious physician who looks upon liquor as a real therapeutic agent. But one cannot be blind to the abuse which led to the writing of the prescription by Dr. Congress.

A corollary of this attitude was that expressed in the New York *Telegram* of May 20

The Volstead Act went too far when it sought to control the legitimate practice of medicine So long as prohibition is the law of the land, however, there is reason in enough regulation to prevent charlatans from abusing their privileges as physicians and becoming in effect, bootleggers

The Wheeling, W Va, *Register* of May 21 under the title "Doctors Shouldn't Misplace the Blame" distinguished between the authority of Congress and of the Supreme Court

To decree that a physician competent to be entrusted with care of the sick may not prescribe for a patient needing stimulation more than one pint of whisky in ten days is quite obviously a foolish use of the statutory power But it is no part of the duty of the Supreme Court to save this nation from folly Its function is to pass not upon the wisdom but upon the constitutionality of laws

The instances of qualified approval and partial disapproval were few A slightly larger number were definitely against removal of the restriction The papers represented in this body of unfavorable opinion include the Mishawaka Ind, *Enterprise*, May 25; Statesville, N C, *Landmark* May 19, Owensburg, Ky, *Messenger* May 19, Sterling Ill, *Gazette*, June 1, Clarksville Texas or Tenn, *Chronicle*, May 18, Bluffton, Ind, *Banner* May 19 Five papers, from small communities in Indiana, Mississippi and Michigan (Union City, Ind, *Times* May 26, Rushville, Ind, *Republican*, May 21; Madison, Ind, *Courier* May 27, Hattiesburg Miss, *American*, May 26, Battle Creek, Mich, *Enquirer News* May 23) have apparently reprinted a syndicated article Thus, the Peoria *Journal* of May 17 concluded its editorial with the two following paragraphs:

The layman is under no delusion as to "prescription" whisky He knows that the physician who 'prescribes' it is merely using his legal authority to collect $3 for writing his name on a blank furnished by the government The 'patient would take no greater chances if he paid his money directly to the druggist or to the messenger boy who makes delivery

If the American Medical Association hopes to denaturize the Volstead act of its hypocrisy it is undertaking a herculean task The real law enforcers are opposed to whisky for all purposes—beverage medicinal and industrial Opponents of the Volstead act, on the other hand are fighting it on all grounds In the meantime, "prescription whisky having been a fake from the beginning, can scarcely be raised in honor by an ancient and noble profession

One wag, on the Nashville, Tenn, *Banner*, is not worried by the controversy Perhaps the nearness of Appalachian fastnesses has kept him mellow On May 20, he wrote

The members of the American Medical Association in Washington are said to have been considering the matter of liquor behind closed doors Well, that's the general custom of the country, isn't it?

PRESIDENT COOLIDGE

Next to the liquor question, the press seized most eagerly on the convention address of President Coolidge The mass of material taken from this address and selected for editorial comment was great, much of it, it seems, was obtained from syndicates As a general summary, apparently independently written, the Trenton, N J *Gazette* of May 19 printed the following, under the title 'Medical Values"

A notable tribute to the physicians of the land was paid by President Coolidge in his address before the American Medical Association Without giving expression to fulsome praise, the President called attention to the high ethical standards which maintain throughout the profession and which are contributing so markedly to the quest for social perfection

Here are a few of the professional qualities to which Mr Coolidge pointed Service, open mindedness heroism, cooperation tolerance and progressiveness And as for the altruism of medical men he declared that they are uniformly willing to serve the interests of human welfare even when such action diminishes the income to be derived from their practice

The President's observations will commend themselves to thoughtful people everywhere Members of the medical profession, owing to self imposed restrictions, usually disdain the plaudits which their services to humanity merit The general practitioner, as well as the laboratory expert, normally fails to receive the public acclaim which is his just due

And so a pleasing element of equity is contained in these remarks of Mr Coolidge Indeed, here is a body of scientists which, as the President noted may well make large contributions to world regeneration, 'physically, mentally and spiritually, when not force but reason will hold universal sway" In voicing this thought, the White House was speaking for America at large

The Indianapolis *News* requoted the tributes paid by the President and concluded

We know of no other group of men who have deliberately set out to destroy the demand for their services By preventing illness through public spirited work for sanitation and hygiene among all people they have reduced the scope of their practice This is in keeping with their vows as men of science and ministers to the needs of the suffering without regard for their own personal welfare The tribute paid to them and their calling by the President was well deserved It is felt by every citizen who has—or should have—a keen sense of obligation to the school which in recent years has added twenty years to his expectation of life

A syndicated editorial appearing in many newspapers of the Middle West including the Gary (Ind) *Post-Tribune*, the Newcastle (Ind) *Courier*, the Riverdale (Ill) *Pointer*, and others concluded

Thus the community owes a big debt to its physicians There are several ways in which we can do something to pay it Many doctors charge little to people of limited means and that generosity is no doubt abused If a person can by any possible effort pay his doctor's bill he should certainly do so and work a little harder to avoid being the recipient of this form of charity

If one could look through the books of the average doctor he would find many accounts due from people who are perfectly able to pay, but fail to do so out of neglect and indifference

The New York *Sun* emphasized the increasing span of life due to the work of medical science

How nobly the doctors have been changing the notions of humanity as to youth and age is shown by the simple fact that Moliere, who died at 51, thought that a man was getting well along in years at 30 an age at which most moderns think themselves rather young to marry

Comparing the practice of medicine with that of law, to the disadvantage of the latter, the New York *Telegram* after pointing out the increasing number of laws on the statute books, said

It would be much the same if young physicians got busy after graduation inventing new diseases or finding new germs, microbes and bacilli with which to infect the human race, so as to make more business and more money for physicians

If President Coolidge gets a chance to address the American Bar Association he might render a public service by inviting attention to the noble example set by the medical profession in their advocacy of prevention

Newspapers everywhere endorsed all the kind sentiments relative to the medical profession expressed by the President, and the Flint (Mich) *Journal* answered well for them

The medical men present knew every fact and every bit of statistics President Coolidge quoted, but this semi official speech of appreciation, expressing the thanks of the nation for the services of its great army of physicians must have been cheering to those who carry on the health work day by day, too often with small thanks for their effort

MEDICAL ECONOMICS

Judging from space used by the newspapers, the public is next most deeply interested in the cost of sickness as presented by President Jackson Again the syndicated article found favor One of these entitled "Paying the Doctor," which appeared in several of the large papers in various parts of the country, is printed herewith

In this day of tonsils and adenoids, paying the doctor has become one of the greatest problems in the life of the average salaried man

The American Medical Association has recognized the burden that the wage earner has to bear and its president, Dr Jabez North Jackson of Kansas City has just issued an appeal for endowment of hospitals for what he calls the great middle class

Doctors have three kinds of patients charity, very rich and those that pay their fees on the instalment plan

The charity patients receive medical attention free it being considered humanitarian for the medical men to volunteer their services to public and charity institutions

The wealthy clients pay fees in keeping with their incomes, thus making up to the physician for the time and expense of caring for his free patients

Those that pay on the instalment plan are the wage earners too proud to accept free medical attention who go into debt and pinch themselves to meet the doctor's bills as well as the bills of the hospitals and the nurses

Being ill is a rich man's luxury or a poor man's paradise, but for the middle man it is a financial calamity

Hospital fees have become so great that only a rich man can afford to pay them The poor man is protected because philanthropists have endowed institutions to provide him with the proper care and attention during illness

> Only the salaried wage earner has been neglected and he must go to the rich man's hospital, pay the rich man's rates and saddle himself with debt in order to get relief.
>
> Not only this: whenever he pays taxes he is paying for the medical upkeep of the poor, for part of this money is used in keeping up hospitals, clinics and other public health institutions.
>
> Whether you call him a wage earner, or a middle man, he does need help and we are glad to see that the American Medical Association is starting a movement for those who aren't rich or poor enough to afford to get sick.

PUBLICITY

Although the public has complained of the hardship involved in paying for medical service, it has not in general resented the fees imposed. It has, however, resented the reticence of the medical profession. Accordingly, a number of newspapers welcomed the address of President Phillips, on which the *Asheville, N. C., Times* commented as follows:

> Without the least modification of its code against personal publicity, President Wendell C. Phillips of the American Medical Association urges the membership to throw off its mask of reticence and its shrinking attitude toward reasonable publicity concerning public health education. Dr. Phillips asserted that the physician has no right to conceal from the nonmedical public the great body of news of first importance which the doctor can communicate. To carry out the purpose proposed, he recommended that the association organize a department of field activity in public health education.

On the same subject, "Uncle Dudley," writing in the Boston *Globe* of May 18, declared:

> The old tradition was founded upon reason, because the tremendous majority were not sufficiently schooled to understand the theory and practice of healing. The spread of education and of the scientific spirit has created a necessity for a new attitude which will make the physician leader in the quest for health. Part of his task is to let people in on secrets.

COSMETICS AND "PATENT MEDICINES"

Although the Winchester, Va., *Star* of May 23 contained an article entitled "Let Them Paint," the Philadelphia *Ledger* of May 18 stated the general agreement with the attitude of medical men toward cosmetics as follows:

> The resolution pending before the American Medical Association proposing that the federal Pure Food and Drugs Act be extended to cosmetics is offered, according to its proponents, to put an end to the use of poisonous and deleterious applications designed to beautify the skin and remove, restore or change the color of the hair.

The Lynchburg, Va., *News* of May 20 printed a novel interpretation of the Association's fight against "patent medicines." Said this journal:

> It is very likely that in many cases medical preparations containing large quantities of alcohol are intended for beverage consumption.
>
> It would be a very bad idea, however, for Congress to attempt to determine what percentage of alcohol is or is not necessary for a medical preparation. That is quite as wrong as for Congress to fix the amount of spirituous liquors that a physician may prescribe. The fact that the doctors are occupying both sides of the fence cannot escape notice.

The Valdosta, Ga., *Times*, however, believed that the inconsistency lies elsewhere; namely, in the work of the Anti-Saloon League:

> Yet it seems that even this dominating and unbending league can compromise its principles at the demand of expediency. It is highly interesting to find the indignant physicians in convention accuse the Anti-Saloon League of countenancing "intoxicants disguised as patent medicines," now flooding the country, some with alcoholic content up to 25 per cent, because these are "consumed in great quantities" in "many strong dry districts," and much dry support would be alienated by hostile move against these "comforting" liquors in disguise. The sick may suffer, but "dry" drinkers must be served! Though Wayne B. Wheeler virtually accuses the physicians of lying, the medical men are provided with a very pointed "comeback."

Not only is the evidence of public trust in the medical profession pleasant to note, it also is gratifying that the public wishes to be informed about the deliberations of the yearly assembly of medical men. Newspaper space is not easily obtained, and the annual session has never before had so large a share of it.

Purposeful Activity Increases Efficiency.—The children of a school class may work with doubled efficiency simply from learning the significance of the work to their wants, and associating the work with sociability, cheerfulness and achievement.—Thorndike: Educational Psychology **3**:128.

Making Most of Physician's Appointment by Court

(Meek v. Wheeler, Kelly & Hagny Inv. Co. (Kan.), 251 Pac. R. 184)

The Supreme Court of Kansas says that in this action under the workmen's compensation act error was predicated on the fact that a physician was permitted to testify that he had made an examination of the plaintiff at the direction of the trial court itself, and because the defendant's counsel argued that fact to the jury as one of special significance tending "to give his evidence greater weight than would otherwise be accredited, and to minimize the weight of other physicians and evidence in the case." But this assignment of error lacked merit. There is a provision of statute (revised statutes of Kansas, 44—516) which indicates a legislative belief that expert witnesses called by the respective litigants may possibly be somewhat biased in their views and that the views of a neutral physician called by the court and under no obligation to either litigant might be helpful in ascertaining the truth touching actual or simulated injuries and incapacity in industrial accident cases. The relative amount of credence to be attached to the testimony of any expert witness, whether avowedly partisan, presumably neutral or manifestly disinterested, like the testimony of any other witness, is a fair subject for debate in addressing the jury. In other words, in an action under the workmen's compensation act, it was proper for the trial court to appoint a neutral physician to examine the plaintiff's physical condition, and it was not erroneous for such physician to testify, among other matters, that he had been appointed by the court, nor for counsel to argue to the jury their views touching the weight and credence which might be given to his testimony because of such appointment.

Damages for Mental Anguish Held Suffered by Child

(Illinois Cent. R. Co. et al. v. Williams (Miss.), 110 So. R. 510)

The Supreme Court of Mississippi, division B, says that the plaintiff when 2 years and 8 months of age was injured by the alleged negligence of the defendant railroad company. His skull was fractured on the left side near the top of the head. A surgical operation was performed in which a piece of the skull about 2 inches long and of the width of two fingers was removed. A small particle of brain came out. The child's mother and father testified that his recovery seemed complete, and that he was more robust and apparently in better health than he was before his injury. The only evidence of physical suffering testified to by them was that he was restless at night, and sometimes would put his hand up to his head and say that his head hurt him. The surgeon who performed the operation testified at the trial, which took place a little less than two years after the injury, that the child appeared to be in good physical condition—in fact, that there had been a complete recovery from his injuries. The trial resulted in a judgment for $20,000 damages, which the court holds was excessive and should be reduced to $15,000.

An instruction given the jury told it that, if it found for the plaintiff, in assessing damages it should take into consideration, among other things, "any mental and physical pain and suffering which the testimony may show he has endured or will endure, if any, as the proximate result of the negligence of the defendant." The defendant contended that a child 2 or 3 years of age could not endure mental anguish, and therefore the instruction authorizing as an element of damages mental anguish already endured was error and misleading to the jury, and probably influenced the verdict. The defendant based its argument on the definition of mental anguish given by the Texas court in *Railroad Company* v. *Miller*, 25 Texas Civ. App. 460, 61 S. W. 978. That court held that mental anguish, for which recovery might be had in an action for personal injuries, included not only the mental sensation or pain resulting from the physical injury, but also the purely mental suffering experienced by the injured person in contemplating his crippled condition and brooding over his future prospects The defendant said that the evidence in the instant case showed that the plaintiff was of such tender years and immature mind that he was incapable of contemplating his crippled condition and brooding over his future prospects That was doubtless true, but the instruction in question did not so define mental anguish According to the Texas court, that is only one of the elements of mental anguish Certainly it is true that, regardless of how immature a child is, it is capable of suffering mental pain as the result of physical injury Mental anguish in some degree necessarily follows physical pain A child, though incapable of reasoning, will cry out as the result of physical pain Mental anguish exists whether the child can recognize it and reason about it or not This court thinks that the instruction criticized by the defendant embodied the correct principles of law.

Not Liable for Abscess After Hypodermic Injection

(Sheehan v Strong (Mass), 154 N E R 253)

The Supreme Judicial Court of Massachusetts says that two separate actions in tort were brought by Mrs Sheehan and her husband to recover for injuries alleged to have been received by her at the private hospital of the defendant in consequence of the negligence of a nurse in his employ The woman's family physician had engaged a bed for her in the hospital and arranged with a surgeon to perform a gallbladder operation Three days after the operation an abscess formed on the right thigh of the patient at a place where an injection of solution of pituitary had been made She testified that during the night following the operation, and while the ward she was in was dark, she felt the nurse rub her thigh with some cold substance and then insert a needle into a different spot from where the cold application was made, and that the nurse seemed to be in a hurry in the manner and method of making the injection She testified further that she believed that this injection caused the abscess The question was whether there was any evidence warranting a finding of negligence if it was assumed that the defendant was responsible for the carelessness of the nurse in administering the injection The defendant offered evidence tending to show that the room was well lighted, that the injection was not hurriedly made, that the place where the needle was inserted was properly sterilized, and that the injection in all respects was properly administered Considering the evidence in the light most favorable to the plaintiff, the court is unable to find any evidence that would warrant a finding of negligence There was no evidence that the hypodermic needle used was infected, or that the abscess was due to an infection The surgeon who performed the operation testified that he did not know what caused the abscess, that if the skin had not been properly washed he could not say that it was the cause, but that it might be He testified further that he would not go so far as to say that the abscess was probably caused by failure to wash the skin, that it might have been caused by a condition of the skin of the patient, or that the solution injected might have been unsterile when it came from the manufacturer On cross-examination he said that if the needle was properly sterilized, but the place where it was inserted was not washed or cleaned, it would not necessarily lead him to believe that an abscess would form There was other evidence offered by the plaintiff tendng to show that she had jaundice and diabetes, and that an abscess would be more likely to develop if a person was suffering from the latter disease Although several physicians testified, none were able to express an opinion as to what caused the abscess In these circumstances there was nothing to show that any act or omission of the nurse resulted in the formation of the abscess Its cause was wholly a matter of conjecture and speculation without evidence to support a finding of negligence on the part of the nurse It followed that the defendant's motion for a directed verdict in each case should have been allowed, and exceptions to a denial of the motion must be sustained, besides, judgment might be entered for the defendant

ASSOCIATION OF AMERICAN PHYSICIANS

Forty Second Annual Meeting held at Atlantic City, N J, May 3 and 4, 1927

(Continued from page 2050)

Cardiac Pain in Rheumatic Fever

Dr Homer F Swift, New York In a study of painful cardiac symptoms in rheumatic fever, two thirds of the patients showed concomitant evidence of cardiac involvement, and one third showed evidence later on Pain in the acute attack was evidence of permanent cardiac injury These studies give indication that when pain does occur the physician should treat the patient as though carditis were present

The Sensibility to Pain of the Pericardium

Dr Joseph A Capps, Chicago There is an impression that pain is the most characteristic symptom of pericarditis, but MacKenzie was impressed by the absence of pain in pericarditis without traces of pleurisy We touched the serous pericardium and sac round the heart through the fourth interspace There was no pain When entry was made through the fifth interspace, there was pain in the phrenic nerve region of the neck Four clinical groups were studied (1) pericarditis, (2) dry pericarditis, (3) cases of coronary thrombosis and (4) cases of pleurisy Large pericardial effusion caused respiratory distress, but no pain Pleural pericarditis caused sharp pain increased by respiration

DISCUSSION

Dr Henry A Christian Boston Clinically, terminal pericarditis rarely gives pain In rheumatic pericarditis, pain is evident There is an idiopathic, acute, nonrheumatic type with sudden onset of severe pain in the abdomen, which is frequently mistaken for a surgical condition The pain is often very severe and continues as long as the persistence of the pericarditis The patients recover, often without subsequent evidence of a lesion The type last mentioned presents considerable diagnostic difficulties unless auscultation is carried out If careful diagnosis is not made, frequently a useless operation is done

Dr Thomas R Boggs, Baltimore I can confirm the observations of Dr Capps in regard to the pain in perforation In a case of pulmonary neoplasm with an enormous amount of fluid, a puncture was made near the nipple When the needle was passed into the puncture, the only points at which the man expressed any feeling of pain were in the region Dr. Capps mentioned

Dr L G. Rowntree, Rochester, Minn I should like to inquire as to seasonal variations, as to the incidence of dyspnea and as to abdominal reference of the pain Absence of pain is one of the most striking symptoms in pericarditis, dry or moist, but without pleural involvement

Dr Homer F Swift, New York The incidence of rheumatic fever shows definite seasonal variation It is highest from February to May, when it begins to drop In severe cases the incidence of dyspnea depends on the underlying cardiac involvement The reference of the pain to the abdomen has not been marked As to the relation of pain to pericarditis, there can be pericarditis without pain, and in other cases there is pain before the pericarditis, hence I feel that the pain is not an indication of the severity of the underlying process I have seen much permanent heart injury from the pericarditis cases Only two patients escaped chronic valvular disease

Dr Joseph A Capps, Chicago There is frequent occurrence of pain in association with pericarditis in rheumatic patients, with a lack of pain in the terminal conditions I would suggest an explanation It may be that in rheumatic carditis we find frequent association with pleurisy, with mediastinitis and involvement of the parietal pleura. In terminal infections, such as nephritis, involvement of the pleura is not so frequent.

Case of Heart Block with Frequent Attacks of Stokes-Adams Syndrome

Dr. James D. Heard, Pittsburgh: This patient suffered with increasing dyspnea, with attacks of mental confusion. He was treated with barium chloride, from 30 to 120 mg. daily, without avail. Studies of the heart one hour after death showed very marked fibrosis with compression of the bundle fibers, and fatty infiltration of the bundle of His.

Occurrence of an Unusual Form of Gallop Rhythm

Dr. Lewis A. Conner, New York: The cases are usually of very short duration. The shock is very marked. The time of the diastolic sound is immediately after the first heart sound. Ten cases were seen. In four it was quite unexpected, occurring in advanced mitral disease. The gallop appears with the beginning of improvement and disappears with its progress. Two patients came back with recurrence of the symptoms. In four cases it was associated with rheumatic heart without signs of failure. One patient had coronary thrombosis. The sound is quick and sharp, and can be seen along the diaphragm. It was occasionally noted with fibrillation. One patient had slow regular rhythm with fibrillation, the slow rhythm probably being a factor. The most interesting change occurring was in the case of hypertension. The location was near the region of the apex. Potin, in 1885, described one case associated with adherent pericardium. The explanation is that it is due to exaggeration of the normal third heart sound.

DISCUSSION

Dr. William S. Thayer, Baltimore: I have been interested in the prediastolic gallop. I think it is commonest in adherent pericardium in acute myocardial disease, in dilated hearts and in aortic insufficiency. The Flint murmur is a loud, early diastolic sound, a little inside the apex of the heart. I think electrocardiograms, when a very exaggerated third sound is heard, are indicative of a grave state of the myocardium itself and are of serious clinical significance. In two cases in which the sound was loudest near the apex of the heart there was a very grave prognosis.

Dr. S. A. Levine, Boston: Dr. Heard made us think that medication would be hopeless in his case, but there have been cases reported in which barium chloride had a valuable effect on the syncope, though not on the heart failure. Barium chloride would be of use for the syncope itself. His case was complicated by heart failure; but without that symptom barium chloride has a definite place in therapy.

Extensive Spontaneous Thrombosis of the Small Branches of the Pulmonary Artery

Dr. Channing Frothingham, Boston: A woman, aged 38, with negative history, had had an attack of shortness of breath six months previously, when she had a cold. Then she improved. Later another cold occurred, with shortness of breath. On admission, the physical examination was negative. On slight exertion there was cyanosis. There was no polycythemia. Liver tests were negative. Roentgen-ray examination showed slight enlargement of the heart. The electrocardiogram did not show anything. The vital capacity was 53 per cent. On the morning of death, the patient was very cyanotic, with the picture of pulmonary embolism. Autopsy showed multiple thrombi scattered through the smaller branches of the pulmonary artery going to the periphery of the lung; slight hypertrophy of the right side of the heart; moderate passive congestion of the liver, spleen and kidneys; slight arteriosclerosis; thrombosis of the hemorrhoidal vein; a small fibroid of the uterus; ulceration of the cervical canal, and slight arteriosclerosis of the pulmonary artery. Some areas were fibrotic, with giant cells and stellate forms. We did not connect these lesions with the multiple thrombosis. In the thrombi, small vessels were working through, showing that the condition was one of long standing. In certain vessels there was a compensatory endarteritis. The cause of the thrombi was not clear.

DISCUSSION

Dr. Homer F. Swift, New York: Were the other organs of the body explored carefully for Aschoff bodies? Von Glahn and Pappenheimer described lesions that on superficial examinations looked like thrombosis, but on examination were found to be definite inflammatory lesions of the vessel wall. Their pictures resemble these illustrations very closely.

Dr. Augustus Wadsworth, Albany, N. Y.: These lesions look like cases of thrombosis and endarteritis which I have described in rheumatic lesions.

Dr. A. S. Warthin, Ann Arbor, Mich.: These lesions look to me like those in Chiari's disease of the liver, extending into the vena cava.

Dr. William H. Welch, Baltimore: Some of the infarcts were anemic necrosis, and some were hemorrhagic. Some of the arteries were occluded without any disturbance in nutrition. Anemic infarcts would show extensive thrombosis of the pulmonary arteries.

Dr. Channing Frothingham, Boston: The arteries elsewhere in the body seemed to be in an excellent condition, except for a few areas of focal sclerosis in the liver. Arteriosclerosis in the lung was shown, but there was no appreciable amount of disease in the wall of the lung.

Experimental Thrombosis

Dr. L. G. Rowntree, Rochester, Minn.: Six or seven per cent of the surgical deaths in Rochester are due to pulmonary embolism. We have tried to avoid these accidents and we believe we have reached a regimen that is effective. We find that heat hastens coagulation time, and cold retards it. To prevent clotting we used heparin, which is an antithrombin. Coagulation is much delayed thereby and clots form slowly, but there is no thrombosis. In jaundiced animals, there was great formation of white thrombi but no fibrin. With many platelets, and without fibrin formation, the blood continued to circulate. Thus it is possible to prevent fibrin formation.

Polycythemia in Feather Dyers

Dr. Eugene S. Kilgore, San Francisco: In July, 1919, there died in the University of California Hospital a German feather dyer, aged 61, who showed clinically a high red count (up to 8,000,000), considerable cyanosis of the nose and ears, palpable spleen, some fibrosis of the apex of the right lung, and, terminally, severe substernal and precordial pain. At autopsy we found erythroblastic hyperplasia of the marrow of the long bones, coronary thrombosis, chronic myocarditis, splenic and renal embolism, and fibrous tuberculosis of the right apex. Two years previously the cyanosis and other physical features were the same but the blood examination was not remarkable. Before his death there came to visit him his assistant in feather dying, a woman, aged 39. Her red cells at one time numbered 12,400,000. She improved following irradiation and benzene treatments.

DISCUSSION

Dr. William C. Stadie, Philadelphia: Was there any appearance of pulmonary fibrosis in these cases?

Dr. Bailey K. Ashford, Porto Rico: In Porto Rico, in the negroes, in the treatment of uncinariasis, followed by excessive anemia, the return of the blood to normal is often followed by an overproduction of red cells. This would seem as if nature, as so often happens, attempts to correct the previous lack by an overcompensation. Thus the mechanism of polycythemia may be in the nature of correction of a previously existing anemia.

Dr. Eugene S. Kilgore, San Francisco: There was a small area of fibrosis in one lung, but not sufficient to have caused any marked effect.

Feeding Whole Liver or an Effective Fraction in Pernicious Anemia

Dr. George R. Minot, Boston: The story of forty cases of pernicious anemia shows that after the feeding of liver (usually 200 Gm. a day) or a certain fraction of it, there occurs with extraordinary regularity a prompt, temporary, often marked increase of the reticulocytes, followed by a rise of the red blood corpuscles, which almost always continues to normal. Kidneys fed to one patient produced similar results. A diet rich in fat does not inhibit the response of the reticulocytes. Raw liver pulp may perhaps cause a greater increase of these cells than an equivalent amount of cooked liver. The behavior of the reticulated red blood cells sugests that liver stimulates maturation of the megaloblasts that crowd the bone marrow in relapse. In secondary anemia the bone marrow does not contain masses of megaloblasts, and a liver diet does not produce a significant increase of reticulocytes. In comparable cases of pernicious anemia the rise of the reticulocytes tends to occur sooner and to be more marked, the greater the amount of effective liver substance fed. The reticulocyte increase is approximately inversely proportional to the height of the red blood corpuscle count. This is to be expected because there are few megaloblasts in the bone marrow when the count of the red blood cells is relatively high. When the count was about one million per cubic millimeter, the reticulocytes increased to between 11 and 50 per cent, and when it was in the vicinity of three million their percentage increase was small. Rarely, a case may show a relatively slight and delayed response of the reticulocytes, which indicates a less desirable prognosis than usual. The nature of the material effective in pernicious anemia is being investigated by studying the influence of feeding fractions of liver. The occurrence or absence of a response of the reticulocytes has given information within nine days after a fraction was fed as to whether or not it was of value. A nonprotein, ether insoluble, alcohol precipitable fraction of beef liver has been isolated, which has caused in each of eight cases a prompt, marked, temporary increase of reticulocytes and a rapid rise in the numbers of red blood cells. Two patients produced at least 750 Gm. of red blood cells in fifteen days while taking about 200 Gm. of this effective fraction. For beneficial results the patient is required to take daily only 10 Gm. of the substance. An adequate, well balanced diet should also be prescribed.

DISCUSSION

Dr. W. C. White, Pittsburgh: Has any attempt been made to estimate the fraction that might be in the Kupffer cells of the liver? We found that a perfusion of the lung had a tremendous effect on the reticulated cells. It had an effect like splenomegaly. Perfusion of the liver might give rise to an effect on the reticulocytes. I believe, however, that we should revise our terminology in regard to some of these elements of the blood. The use of the word reticulocyte is especially misleading.

Dr. Bailey K. Ashford, Porto Rico: In the so-called pernicious anemia following sprue, we have used liver treatment with excellent results in a small series of cases.

Dr. Henry A. Christian, Boston: It is interesting to have watched the enthusiasm accorded to various forms of treatment that have arisen. This is the first type of treatment that to my mind justified the enthusiasm of its advocates. The reasons are these: It is easily applied; it has always worked, and the improvement in the clinical appearance is even more striking than the charted rise in the reticulocytes and the later rise in the red cell count. This treatment has best stood the clinical test in twenty-two years of experience.

Unusual Types of Hemorrhagic Disease

Dr. H. Z. Giffin, Rochester, Minn.: I have seen five unusual types of hemorrhagic disease: 1. A case of splenic anemia and hemorrhagic purpura which developed simultaneously; cure followed splenectomy. 2. Severe hemorrhagic disease in women, through four generations, with high platelet level, long prothrombin time, but normal coagulation time. 3. Severe hemorrhagic disease, presenting the features of hemorrhagic purpura, except for thrombocytopenia; improvement occurred with splenectomy. 4. Severe hemorrhagic disease with very high viscosity of the blood, the platelet level being low and viscosity 31. There was very severe bleeding. The patient was a missionary who came from Thibet. Coagulation time was prolonged and prothrombin moderately prolonged. Albumin was 22 per cent and globulin 78 per cent, a reversal of the normal ratio. 5. Familial epistaxis with telangiectasis, and low platelet level.

Hypertensive Encephalopathy

Dr. B. S. Oppenheimer, New York: There are many acute cerebral upsets, such as convulsions, transient aphasias, hemiplegias, sudden deafness, and amauroses which are related to states of hypertension. We have termed this encephalopathy. A boy, aged 19, who was twenty months in the hospital with marked hypertension after pneumonia but without evidence of disturbed renal function, had violent cerebral convulsive attacks, associated with rise of blood pressure, somewhat analogous to toxemia of pregnancy or acute lead poisoning, not due to disturbance of renal function but rather to some local cerebral change, perhaps sudden arterial contraction, producing sudden edema. Probably vasoconstriction is the primary cause and edema is secondary.

Relation of Acute Infection to the Onset and Progress of Glomerular Nephritis

Dr. Warfield T. Longcope, Baltimore: We have investigated the association of acute infection with the onset of glomerular nephritis and the association of acute infection with the progress of the nephritis. Forty cases have been studied of acute and subacute glomerular nephritis in persons under 30 years of age. Many were studied in detail. Thirty-four cases were associated with acute infection. Tonsillitis occurred in highest proportion in these cases, and 81 per cent were associated with *Streptococcus hemolyticus*. Ten patients recovered, with subsidence of the infection. Three patients died from persistence of the infection. In 83.3 per cent of the cases of nephritis which have progressed or remained stationary the infection has persisted, or the organism has persisted in the pharynx. The alpha and beta types of *S. hemolyticus* produce toxic filtrates in large amounts. There is no evidence that *S. hemolyticus* produces nephritis by direct infection of the kidneys, but patients become highly susceptible to the toxins.

DISCUSSION

Dr. C. P. Emerson, Indianapolis: Has any particular attention been paid to the site of the operation which was followed by acute exacerbation? In our practice we have stipulated to the tonsil men that they are allowed only two minutes for the removal of the tonsils, thus avoiding as much as possible trauma of the tissues with spread of the infection. When this program has been strictly carried out we have had no trouble with subsequent infection of the pharyngeal tissues.

Dr. Homer F. Swift, New York: Were any studies made of the antitoxic capacity of the blood in these cases? In a person harboring toxins, when the organism persisted, we found that there was a demonstrable amount of antitoxin produced in the serum.

Dr. A. R. Dochez, New York: A great deal of interest attaches to the nature of the so-called antitoxin in these cases. The term is used somewhat loosely. Most bacteria give off substances that produce reactions in the skin. Diphtheria toxin produces an acute reaction in the skin. Some of the substances are readily neutralizable, as for instance, diphtheria, which can be neutralized by serum. Tuberculin cannot be neutralized by any serum. Although these studies are incomplete on these substances, which may be single or consist of more than one substance, there should exist a degree of neutrability which varies from the status of diphtheria antitoxin to substances more tuberculin-like in nature. Until there is better understanding as to what is meant by soluble bacterial toxins, it is difficult to estimate their neutralizability.

Dr. Warfield T. Longcope, Baltimore: In answer to Dr. Emerson, we have waited until the acute phase has subsided before operation was performed, but in some cases a necessary tonsillectomy or adenectomy was done promptly. In operations which are more protracted, such as drainage of a sinus, there is often exacerbation, but there was none after tonsillectomy unless there was secondary infection. We have done some work in trying to neutralize the toxins with the serums of the patients, but not enough to justify conclusions. In one instance we thought we obtained neutralization.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Factors of Growth Regulatory Nature in Tissue Cells. A. Fischer, Copenhagen.—p. 562.

Chronic Ulcer and Carcinoma of Stomach.—MacCarty's analysis of chronic ulcer and carcinoma of the stomach is based on 967 cases of ulcer and 1,353 cases of carcinoma.

Infectious Mononucleosis. — Twelve cases of infectious mononucleosis are reported by Cottrell. The clinical and hematologic pictures seem sufficiently distinct and definite to justify the conclusion that the condition constitutes a clinical entity. The salient features are: 1. The usual general symptoms of an acute febrile disease of greater or less severity. 2. An increase in the lymphocytes, amounting to 40 per cent or more of the total leukocytes. 3. Lymphadenopathy. 4. Angina—either hyperemia of the fauces and pharynx, or a severe ulcerative and exudative process involving the tonsils, uvula or pharyngeal wall, or all three. 5. Splenomegaly. 6. The common presence of the organisms of Vincent in the ulcerative and exudative lesions. 7. Increase in the total number of leukocytes. The prognosis is invariably favorable, and complications are almost unknown.

Histology of Infectious Mononucleosis.—The histology of infectious mononucleosis, in Fox's opinion, seems not to be very distinctive, unless it is that there is a marked hyperplasia of all elements, with an attempt to retain the architecture of the lymph nodes.

Hodgkin's Disease of Skin.—Urticaria-like lesions of the skin preceded by many months the other manifestations of Hodgkin's disease in Bine's case. These skin lesions cleared up, but in later stages of the illness, lesions of the mucous membranes appeared, with marked destruction of tissue. At necropsy the appearance of the tissues was so unusual that, until a thorough microscopic study had been completed, the pathologist doubted the correctness of the clinical diagnosis. There was absence of the usual gland enlargements. The suprarenals were fully the size of lemons, and suggested tuberculosis, even though other tuberculous lesions were absent.

Renal Glycosuria and Pentosuria.—Jones and Sussman assert that the differential diagnosis between renal glycosuria and diabetes mellitus is made by the blood sugar estimation; the blood sugar tolerance test, and the estimation of the respiratory quotient after carbohydrate ingestion.

Peritoneal Absorption.—Experiments made by Morton on rabbits and dogs show that phenolsulphonphthalein is absorbed at essentially the same rate from the inflamed and the normal peritoneum, both in mechanical and bacterial peritonitis. An exception noted was that an adhesive type of peritonitis, greatly lessening the peritoneal area, did seem to retard the rate of absorption slightly. It was further concluded that the presence of a hypertonic solution of sugar in the peritoneum did not retard the absorption of the dye.

Treatment of Whipworm Infestation.—Of the eleven cases reported by Lieb, in only one did the patient's symptomatology suggest parasitism. The other ten cases were discovered simply through accidental observations in routine feces examinations of patients suffering from various symptoms. The time honored methods of parasite eradication by means of anthelmintics failed in all but three of the cases. The treatment that was successful in the remaining cases is described as follows: The patient is given 2 ounces (60 cc.) of castor oil and is then placed on a low residue diet. Then, on each of four successive days, he is given a 2 liter enema with 0.5 per cent solution of monohydrated sodium carbonate, to which is added 1 ounce (30 cc.) of colloidal kaolin. Kaolin is also given by mouth, in 1 ounce doses, once daily, on each of these days. The alkali is given for the purpose of dissolving the mucus. The kaolin tends to cut the thicker mucus and mechanically "de-mucuses," so to speak, the wall of the entire colon. After this four day treatment, the kaolin is discontinued, but the alkaline enema is continued for two days or more. After complete expulsion of this enema, 8 ounces (236 cc.) of crude oil is injected into the rectum through a large syringe, and the patient instructed to retain it as long as possible.

Infection of Gallbladder in Pernicious Anemia.—In every case of pernicious anemia with which Jones and Joyce have personally worked, a chronic infection of the gallbladder has been demonstrated. A small group of cases, which resembled mild pernicious anemia, possessed the same type of biliary infection, and on removal of the infection, the patients were restored to fairly normal health.

Intradermal Salt Solution Test in Scarlet Fever.—The time required for disappearance of the wheal made by injecting salt solution intradermally was found by Lovett to be shortened in scarlet fever, with the amount of shortening roughly proportional to the severity of the illness. In the absence of complications the time returned to normal rapidly, usually before the patient was ready to be out of bed. Urticaria was associated with a shortened disappearance time. A disappearance time of less than thirty minutes may be taken as an additional indication, besides the patient's general condition, for giving scarlet fever antitoxin.

Hemihypertrophy and Twinning.—The literature on fifty-three cases of hemihypertrophy is reviewed by Gesell, and two new cases are reported.

Electrocardiogram in Bronchial Asthma.—Of fifty cases of bronchial asthma and emphysema reported on by Kahn, ten showed electrocardiographic evidence of right ventricular preponderance. The remaining cases either did not show preponderance electrocardiographically or showed left ventricular preponderance in about equal number. Among these, a large proportion of cases showed hypertension and aortic atheroma—factors which influenced the hypertrophy of the left ventricle to a degree sufficient to mask the electrocardiographic evidence of right ventricular hypertrophy. Four of the cases showing right ventricular preponderance also showed high P_2 and P_3. Inversion of the T wave in lead III did not show any particular relation to the ventricular predominance.

Heart Disease Complicating Pregnancy. B. E. Hamilton and F. S. Kellogg, Boston.—p. 535.
*Developmentally Unfit Infant. G. van A. Brown, Detroit.—p. 541.

Postpartum Care.—In Polak's opinion, more than 60 per cent of the lesions which make up the diseases peculiar to women are the direct results of poor midwifery, the incidence of trauma, infection and a lack of appreciation of the physiologic and biochemical processes which take place in involution. He describes the methods that he employs to prevent disastrous results. Speaking of the pessary, he says: "The large majority of acquired retroversions, provided the patient has intact structures, if treated before they become flexions, can be relieved and many times permanently cured with the pessary."

Results of Cervical Cesarean Section.—A series of forty-one repeated cervical cesarean sections has convinced Phaneuf that the operation is sound in principle, easy of performance and remarkably free from untoward aftereffects. The convalescence is more nearly that of a pelvic delivery, as the lack of handling of intestines reduces shock and distention to a minimum.

Puerperal Infection Due to Anaerobic Streptococcus.—In many of these cases, Schwarz and Dieckmann isolated *Streptococcus putridus*, but they are convinced that other types of anaerobic streptococci which they have encountered are also able to produce pathogenic lesions, but do not do this to the same degree as the organism which Schottmüller described. They advise that in cases of pelvic thrombophlebitis due to anaerobic organisms, particularly *Streptococcus putridus*, ligation of all pelvic veins should be attempted. If the patient's condition justifies further procedure, the infected uterus with the tubes and ovaries should be removed, both to remove the infection of the uterus and to limit the degree of pelvic edema which results from ligation of this kind. If the best results are to be obtained from such a procedure, it must be done as soon as the organism has been recovered from the blood stream in connection with a chill. It is also important to cleanse the uterus early in all cases in which there is a profuse foul discharge.

Rectal Ether Anesthesia in Labor.—Harrar has used rectal ether anesthesia in 580 cases of labor with very satisfactory results. He has not seen any ill results to the mother, and the usual disadvantages of other methods of easing pain in childbirth—perineal delay and asphyxia of the new-born child—are not in evidence. In comparison with the Freiburg "Dämmerschlaf," the effect produced on the mother's suffering is very similar in typical cases; but there is no inhibition of good bearing down efforts in the second stage, and there are no alarms regarding the respiratory condition of the child at birth. Rectal analgesia especially takes the place of intermittent nitrous oxide gas anesthesia during the last few hours of labor. Since it is simple it can be used in the home without the service of a skilled anesthetist.

Conduct of Obstetrics.—Gordon believes that there is a rapidly widening gap between the specialist, on the one hand, and the average man, who handles the bulk of obstetrics. He says hospitals might well open their doors for the practice of obstetrics to all those near them who will agree to follow the rules for technic, consultations, and operative deliveries, and to report their difficulties and casualties at the staff conference. Not the training of more specialists, but continuous education of the average man is important. That means graduate education, not by providing courses for those who seek them, but by the organization of hospitals everywhere, making available for all the vast amount of clinical material which passes through their wards, and carrying to all clinical opportunities for a review of their own experiences which are now denied them. Hospitals will then arrive at their full measure of usefulness, and physicians will discharge their obligations to the public and to one another.

Developmentally Unfit Infant.—Brown says that the best treatment for the developmentally unfit infant is well illustrated in Maeterlinck's play the "Bluebird," in which we are taken to the "land before birth" where children are waiting to be born, having selected their parents-to-be; or in the advice of Oliver Wendell Holmes to children "to choose good grandparents." When the average man learns that he is spending an enormous portion of his wages to insure his family against disease, when a wise marriage would have given him this insurance free of charge, he is bound to be impressed.

Neuropsychiatric and Disabled Wards of United States Government. J. J. Kindred, Queensborough, N. Y.—p. 711.
Determination of Intellectual Regression and Progression. G. van N. Dearborn, Kingsbridge, N. Y.—p. 725.

Infantile Convulsions.—The figures given by Thom indicate that infantile convulsions occur sixty-seven times in every thousand cases, or about once in every fourteen cases. In 265 cases, quite unselected, reports of which were gathered from a house to house canvas, 29 per cent of the patients were either mentally retarded or epileptic. There was little or no relation between the exciting factor of the first convulsion, that is, whether it was associated with trauma, gastro-intestinal upset, or an acute infection, and the likelihood of the convulsion's persisting or the child's intellectual equipment being impaired. Of the 265 patients forty-two, or 16 per cent, were mentally deficient, and thirty-five, or 13 per cent, were continuing to have convulsions. The incidence of mental deficiency and epilepsy was almost twice as great in those cases in which there was no apparent exciting cause for the first convulsion. Those cases in which the convulsions occurred without any apparent exciting factor (that is, without trauma, teething or gastro-intestinal upsets) are invariably more significant, and the prognosis should be more guarded than in cases in which the convulsion is associated with some definite cause. In a fairly large group of cases, the convulsion is only a symptom of an unstable nervous system, one that is unable to withstand the ordinary vicissitudes to which the normal child is subjected. There is undoubtedly a fairly large group of convulsive disorders in childhood, in which the convulsions are symptoms of an undiagnosed meningitis or encephalitis, which leaves behind irreparable injury to the nervous system. The convulsion itself, though not associated with any devastating disease, such as meningitis or encephalitis, may produce injury from which the brain never recovers. The convulsions associated with rickets and tetany may leave behind very definite injury to the nervous system. There is reason to believe that if the infantile convulsions associated with rickets, gastro-intestinal upsets and acute infections were looked on more seriously, and a greater effort was made to prevent their occurrence during early life, much epilepsy and mental deficiency might be prevented.

Care of Tuberculosis Patients in Mental Hospitals.—Klopp shows that there has been definite progress in the care, treatment and segregation of tuberculous patients in mental hospitals, but that there is room for further improvement.

Treatment of Milk by Electricity.—Prescott experimented for one year with the electrical treatment of milk proposed by the Medical Research Committee of Great Britain in 1914. The milk did not at any time give a cooked taste, the cream line was well marked, and the volume of cream appeared as in untreated milk. The keeping quality was excellent. The studies on the reduction of the number of bacteria have shown, in general, a high efficiency. An average count of about 20,000 thermophilic organisms per cubic centimeter was obtained in the raw milk, and about 80 per cent of these were destroyed by treatment. Studies on some of the surviving types of bacteria gave, as common survivors, one strain of chromogenic sarcina, one chromogenic micrococcus, and three spore-forming rod-shaped bacteria, of which two grew readily at from 50 to 55 C. Colon bacilli were not found in the samples of treated milk. Tubercle bacilli do not survive.

American J. Roentgenol. & Rad. Therapy, New York

17: 405-506 (April) 1927

Roentgen-Ray Diagnosis of Colitis. J. L. Kantor, New York.—p. 405.
*Roentgenologic Sign of Mucous Colitis. A. W. Crane, Kalamazoo, Mich. —p. 416.
Roentgen-Ray Diagnosis of Lesions of Upper Urinary Tract Unassociated with Calculus. W. M. Shaw, Jacksonville, Fla.—p. 426.
Obstructive Emphysema: Case. J. A. Wilson, Washington, D. C.—p. 432.
*Roentgenologic Study of Chest in Terminal Stage of Pulmonary Tuberculosis. F. K. Herpel, West Palm Beach, Fla.—p. 436.
Roentgenographic Estimation of Concentration of Tetraiodophenolphthalein in Gallbladder. R. R. Newell, San Francisco.—p. 443.
*Traumatic Pneumoventricle of Cerebrum. S. C. Davidson, Rochester, N. Y.—p. 447.
Chondroma of Vertebrae: Case. R. J. May, Cleveland.—p. 452.
Horseshoe Kidney: Case. R. M. Lecomte, Washington, D. C.—p. 456.
Treatment of Uncontrollable Adolescent Bleeding with Radium. W. Neill, Jr., Baltimore.—p. 461.

Roentgenologic Sign of Mucous Colitis.—The sign, described by Crane as the string sign, depends for its significance on the continuity of this mucoid material within the colon. The string sign may involve any part of the colon, the ascending colon least often, the transverse only at times, most often the descending colon and rarely the sigmoid.

Stereoscopic Roentgenography of Tuberculous Chest.—The bodies of 100 persons, dying in a hospital devoted to the care of the tuberculous, have been examined by Herpel by stereoscopic roentgenograms of the chest. Certain tables have been worked out in the analysis of these roentgenograms, showing the incidence of various types of tuberculosis in these patients, with data concerning the pleural complications, the condition of the heart, cavitation and fibrosis. A high percentage of acute miliary tuberculosis was present in this series of deaths from tuberculosis; 23 per cent of the deaths were due to typical acute miliary tuberculosis. Approximately 25 per cent of the patients in this series presented, both from a roentgenologic and a pathologic standpoint, evidences of a combined tuberculous and syphilitic process.

Traumatic Pneumoventricle of Cerebrum. — Two cases of traumatic pneumoventricle of the cerebrum are reported by Davidson, with a mortality rate of 50 per cent. The condition follows fracture of the skull, when the fracture is in such a location as to permit the entrance of air into the cranial cavity. The most probable route by which air gains entrance into the ventricles of the brain is by means of the subarachnoid space.

Cardiospasm Complicated by Pulmonary Abscess. P. P. Vinson, Rochester, Minn.—p. 359.
*Abdominal Injury. H. B. Eisberg, New York.—p. 362.

Operation for Talipes Cavus.—The principle of the operation which Rugh first described in 1919 is the removal of the structure that is primarily responsible for the deformity, and that is the cause of the relapse and of the continued progress of the deformity, and its replacement by a fat and fascia flap taken from the patient's leg.

Abdominal Injury.—Eisberg relates the case of a boy who fell on his abdomen while hitching on an automobile. The preoperative diagnosis was (1) rupture of the rectum, with extrusion of the small intestine through the anus, and (2) fractured pelvis. When the abdomen was opened, a loop of ileum 60 cm. long was found torn from its mesentery, which passed through a rent in the mesosigmoid from right to left and downward through a tear in the posterior parietal peritoneum, approximately over the sacro-iliac synchondrosis. Further examination revealed the same loop passing downward behind the rectum, which was stripped from the hollow of the sacrum and had a laceration 5 cm. in length, 2 cm. above the anal margin, through which this same loop passed and finally protruded from the anus. A postmortem roentgen-ray examination showed a fracture through the left acetabulum, and a crushing fracture of the fifth lumbar vertebra. Autopsy verified these observations and disclosed, in addition, a partial dislocation of the sacro-iliac synchondrosis.

Serologic Measure of Tuberculosis. A. Vernes, Paris.—p. 505.
*Refraction and Colloid Lability of Blood Serum in Tuberculosis. J. de Darányi, Budapest.—p. 510.

Relation of Milk to Tuberculosis. — Park discusses the extent of human tuberculosis due to the bovine bacillus, and the practicability of reducing or eliminating it by the destruction of the tubercle bacilli in milk and milk products, or by the elimination of the infection of milk by preventing tuberculosis in cattle. He says that the amount of tuberculosis due to the bovine type has decreased more than that due to the human type in cities where pasteurization is in operation.

Vernes Test for Tuberculosis.—Baylis regards the Vernes test for tuberculosis a distinct contribution to serologic methods in the diagnosis of tuberculosis, and a guide to treatment.

Colloid Lability of Blood Serum in Tuberculosis. — De Darányi avers that the colloid lability reaction indicates the activity of the tuberculous process. In incipient cases refraction is still normal, and colloid lability in most cases, if not strong, is already positive. In chronic tuberculosis both values are increased. In grave cases, there are low refraction values with very strongly positive colloid lability. In serial examinations, the increase of refraction and colloid lability means a progression of the tuberculosis, and the decrease of both that healing is taking place. An increase of colloid lability to strongly positive reactions, with a diminution of refraction, that is, an inverse progression of both values, indicates a bad prognosis, especially if hyporefraction values are reached.

Boston Medical and Surgical Journal

196: 635-676 (April 21) 1927

Diagnosis of Abdominal Emergencies. J. M. Birnie, Springfield, Mass. —p. 635.
*Primary Carcinoma of Pancreas. B. M. Fried, Boston.—p. 640.
Conservative Treatment of Optic Nerve Disturbances from Focal Infection. L. E. White, Boston.—p. 644.
*Low Protein Diets in Chronic Nephritis with Nitrogen Retention. M. Smith, Boston.—p. 649.
Directory for Wetnurses. F. B. Talbot, Boston.—p. 653.

Primary Carcinoma of Pancreas.—In the case reported by Fried there was a history of excruciating epigastric pain of one year's duration in a man, aged 70. At the necropsy, Fried found a primary carcinoma of the tail and the body of the pancreas, with metastases to the lungs and the liver.

Low Protein Diets in Chronic Nephritis.—Smith shows that diets of lower protein content than are commonly used in the dietary treatment of chronic nephritis with nitrogen retention are feasible. The amount of protein allowed in the diet should be based on the amount of nonprotein nitrogen which the patient is able to excrete during twenty-four hours. If the nitrogen retention is to be relieved, the protein nitrogen in the diet should be less than the total twenty-four hour content of nonprotein nitrogen in the urine. When the twenty-four hour nitrogen excretory capacity of the kidneys equals the amount of endogenous nitrogen catabolism, it will be impossible to relieve nitrogen retention by dietary measures. With properly constructed diets, it is approximately accurate to calculate the endogenous nitrogen catabolism at from 0.02 to 0.03 Gm. per kilogram of body weight in twenty-four hours. When any subject partakes of a diet which satisfies the energy requirements in full, but with a protein nitrogen content of less than 1 Gm., there is, at first, a strong negative nitrogen balance, and then this gradually diminishes until it approaches a minimum. If such a diet is indefinitely prolonged, it might be possible to deplete the body protein to a dangerous extent. However, there is sufficient evidence to show that such a point would not be reached for many months. This fact makes it practical to administer diets of very low protein content to patients with chronic nephritis and nitrogen retention, for when chronic nephritis has progressed to such an extent as to make necessary diets practically free from protein, other complications of the disease will be more apt to prove fatal sooner than the effects of protein starvation can become apparent. These measures are highly practical in rapidly relieving nitrogen retention, which is the result of excessive protein intake in the presence of a moderate degree of renal insufficiency. After relief of retention, a protein intake could be given which would ensure nitrogen balance.

Effect of Injection of Iodized Oil.—Although iodized oil can be given with impunity in most cases, the Ballons say that it should not be injected in cases of pulmonary tuberculosis of the exudative type nor in tuberculous pneumonias, as immediate reactions are produced and its persistence produces ill effects. Selected cases of the surgical type of pulmonary tuberculosis are usually suitable cases for injection, and do not produce any reactions. The persistence of iodized oil in a tuberculous lung free from abscess or bronchiectasis is about the same as in the normal lung.

Diverticula of Appendix.—Chase is of the opinion that this condition is more common than is generally realized. It offers one explanation of the recurring, so-called subacute appendicitis extending over months or years, and terminating quite unexpectedly and rapidly by perforation which is otherwise unexplainable. Three cases are reported.

Urine in Diabetes Insipidus.—In a case of diabetes insipidus, Illievitz failed to find either inosite or creatinine in the urine. The urine of diabetes insipidus apparently does not contain any substance which itself may be the causative factor of the polyuria. A substance of unknown chemical composition was isolated from the urine. This was not found in the urine when polyuria was experimentally induced. The substance was isolated and found to be viscid, insoluble in water, but soluble in ether and chloroform; it was partly soluble in 75 per cent alcohol, but could be precipitated with absolute alcohol, forming a fine, amorphous, purplish sediment. Strong and weak acids do not affect it, but it is slowly and totally soluble in strong alkalis, forming a colorless solution, and can be reprecipitated by means of strong acids. An attempt to establish its relationship to indican or tryptophan failed. The urine from which the unknown substance was extracted did not contain either indican or tryptophan.

Blood Transfusion in Bronchial Asthma.—Blood transfusion was done by McBroom in five cases of bronchial asthma. A child and two young men are well today, and have not had recurrences. Two older persons are improved but not altogether free of their trouble.

Treatment of Postoperative Vomiting.—To prevent postoperative vomiting, Dolan gives 100 cc. of orange juice by mouth, with 5 units of insulin hypodermically, one-half hour before anesthesia. Three hours after operation, 100 cc. of 20 per cent dextrose solution is given hypodermically or intravenously.

Influenza Encephalitis.—Since other types of encephalitis than the lethargic are common, the term "influenza encephalitis" is suggested by Patton, restricting the use of the word "lethargic" to the first type, and giving the name "myoclonic" to the second and "maniacal" to the third type. He also asks, Can it be that the disease is a septicemia or bacteremia due to the influenza organism? Believing the disease to be a septicemia, he gives intravenous injections, daily, of from 10 to 15 cc. of a 0.5 per cent solution of neutral acriflavine in physiologic sodium chloride solution. He reports good results.

Agranulocytic Angina.—In the case reported by Prendergast, the hemoglobin was 25 per cent, and the leukocytes, 10,000 per cubic millimeter. The blood smear showed pale red cells, and the platelets and leukocytes appeared decreased in number. There were 90 per cent apparently normal small lymphocytes, and 10 per cent large lymphocytes. No polymorphonuclear or granular cells of any sort were seen.

*Distribution of Jaundice in Circulatory Failure. J. Meakins, Montreal.—p. 135.

Estimating Velocity of Blood Flow.—A new method is presented by Blumgart and Yens for the measurement of the velocity of blood flow in man. The active deposit of radium is injected into the antecubital vein of one arm, and its time of arrival in the other arm is detected by means of a modified C. T. R. Wilson cloud chamber device.

Normal Velocity of Blood Flow.—The circulation times of fifty-three normal resting male individuals are presented by Blumgart and Weiss. The average arm to arm circulation time was eighteen seconds. The average arm to arm circulation time when reduced to square meter of body surface was ten seconds in individuals between the ages of 15 and 29, and eleven seconds between the ages of 30 and 75. With a conspicuous increase in the pulse rate there is a slight but definite tendency toward an increased velocity of blood flow. A relatively low ventricular rate does not seem to lower the velocity of blood flow below that exhibited by individuals with higher ventricular rates. Normal variations in the blood pressure bear no relation to the normal variations in the velocity of blood flow.

Estimating Inorganic Sulphates in Blood.—Loeb and Benedict used the gravimetric method in their work. They found that the concentration of sulphate ion in the blood of patients suffering from cardiac and renal disorders is at times markedly increased, and that it nearly parallels the retention of nitrogen. There is little deviation from the normal sulphate ion values in certain other pathologic conditions. The normal sulphate ion content of serum varies between 0.40 and 1.00 milli-equivalent per liter. In nephritis with nitrogen retention, the sulphate ion is retained in the blood and roughly parallels the nonprotein nitrogen. Inorganic sulphate ion plays a relatively important rôle in the partition of the acid radicals in the blood in nitrogen retention nephritis.

Preferential Utilization of Carbohydrates in Diabetes.—A new method of studying the question of preferential metabolism of certain carbohydrates or related substances is presented by Campbell and Markowitz. This consists in feeding to depancreatized animals receiving insulin known quantities of the test substance in substitution for equal amounts of glucose. The results obtained by this method on levulose, inulin, dihydroxyacetone and glycerin do not afford evidence that greater quantities can be utilized by the diabetic organism than of glucose itself. This suggests that these substances must pass through a glucose phase in their metabolism and therefore do not undergo any preferential utilization as compared with other carbohydrates. The application of these results to the treatment of human diabetes mellitus is indicated.

Welch Bacillus in Stool in Pernicious Anemia.—Nye asserts that in stools from cases of pernicious anemia there is a great increase in the number of *Bacillus welchii* spores, as compared with normal stools and the stools from the majority of cases of miscellaneous disease. This same increase in *B. welchii* spores is also present in stools from cases of gastric achylia without pernicious anemia. Counts of vegetative forms would seem to indicate that in any of the foregoing conditions the number of active or vegetative forms of *B. welchii* present in the stools is practically the same. On the basis of these observations and the tendency of *B. welchii* to form spores in alkaline mediums, Nye says that it seems logical to assume that the spore increase in pernicious anemia is secondary to the gastric achylia rather than indicative that pernicious anemia is caused by chronic intestinal infecton with *B. welchii.*

Studies on Obesity.—Studies on five cases of obesity in which the patients were maintained on subcaloric diets for prolonged periods of time are reported by Mason. In all cases the ketogenic-antiketogenic molecular ratio exceeded 1 : 1. In one case, the same ratio exceeded 1 : 2 throughout an experimental period of seventy consecutive days. In no case, during the experimental periods, was there any evidence of ketosis.

Oxyhemoglobin Dissociation Curves in Anemia.—The oxyhemoglobin dissociation curves of the whole blood of several subjects with anemia, primary and secondary, were investigated by Richards and Strauss at serum p_H of 7.24, 7.44 and 7.64. At the lower p_H values, all curves studied were close to the curves of normal blood. At serum p_H 7.64, the anemia curves were definitely lower than the normal. Points on the curve of a patient with polycythemia vera did not show evidence of abnormality.

Blood Urea Concentration.—Data are presented by the MacKays that show that the blood urea concentration increases slightly with any reduction from the normal amount of functioning renal tissue, but does not begin to rise markedly until the kidneys are reduced to less than half their original size. Beyond this point the blood urea concentration rises with increasing rapidity to higher and higher levels as the amount of renal tissue is still further decreased. The interesting fact is brought out that a patient with chronic interstitial nephritis may have a blood urea concentration which is within the limits of normal, even though only 50 per cent of the normal amount of functioning renal tissue remains.

Jaundice in Circulatory Failure.—Meakins reports six cases. The pigmentation of the skin in jaundice would appear to be due to the disposition of bile pigments in the cellular elements rather than to a diffusion of the pigments into the intercellular spaces. Microscopic examination of the skin and other tissues shows the cells themselves to contain deposited bile pigments. If the bile pigments were not in solution in the intercellular spaces, it would explain the isolated observation that jaundice of the skin may occur in edematous areas, provided the jaundice antedates the occurrence of the edema. In this one instance the skin was pigmented, while the edema fluid was free of bile pigments. It would appear that an adequate explanation of the absence of bile pigments in edema and serous fluids is not yet possible.

Rapid Method for Determination of Chlorides in Blood or Urine. S. L. Leiboff, New York.—p. 702.
Estimating Blood Pressure in Rabbits. E. M. Watson, London, Can.—p. 706.

Nephelometry.—Kleinmann describes a new nephelometer designed by him and gives a new standard of turbidity. He stresses the fact that nephelometry has proved eminently useful in microchemical and biologic research.

Diffuse Cortical Sclerosis.—Two cases of diffuse cerebral sclerosis are reported by Rusk and Nixon, the ages of the patients being 1 year and 5 months, and 2 years and 10 months, respectively. In both cases the family history was negative, and there was nothing significant in the past history. Vision was involved in both children, and hearing in the second and probably also in the first. The first child was definitely rigid when first seen, and the deep reflexes were hyperactive at that time; later, there was little rigidity and the knee jerks could not be obtained. The second child was spastic and had exaggerated deep reflexes, except in the right leg where a flaccid paralysis developed while the child was in the hospital. In neither case were there pathologic reflexes. Both cases present in a general way a similar pathologic picture. Grossly, there was a striking diffuse, symmetrical atrophy of the cerebral convolutions, with wide but rather shallow sulci in brains which presented normally disposed fissuration. The fresh brains had an elastic firmness to the touch. The microscopic picture consisted of an enormous overgrowth of the glia tissue in the cortex and, to a much less extent, in the white matter of the brain, basal ganglions, brain stem and cord, with marked involvement of the cortical nerve cells and, to a less degree, of the nerve cells of the basal ganglions, brain stem and spinal cord.

Hemoglobin and Erythrocytes in South.—Lippincott asserts that the normal average hemoglobin percentage and erythrocyte counts are lower in Mississippi than the usually accepted normal standards. Color indexes average slightly below 1. While erythrocyte counts do not change with the seasons as does the hemoglobin, most of the higher counts occur in the colder months.

Columnar Arrangement of Primary Afferent Centers in Brain Stem of Man. W. Freeman, Washington, D. C —p 378.

Intraventricular Hemorrhage.—Sands and Lederer report three cases. Premonitary symptoms of intraventricular hemorrhage are absent. The headache, dizziness and fainting spells which were present in two of these cases pointed to the concomitant cerebral arteriosclerosis. The last case, in which aneurysms were found, presented a chain of symptoms frequently seen in cases of ruptured intracranial aneurysms.

Treatment of Epilepsy.—Klein and Forcione did not derive benefit from the use of calcium over four and five month periods in various types of epilepsy. Not only was there no diminution in the number of seizures, but there was a tendency toward an increase. No advantage was seen in the use of glucocalcium over calcium chloride. There was not a sustained increase in the calcium concentration of the blood serum after the injection of from 0.5 to 2 Gm. of calcium salts.

*Quantitative Comparison and Toxicologic Study of Ephedrine and Epinephrine. J. E. Nadler, Woods Hole, Mass —p. 489

Treatment of Achlorhydria.—A patient with achlorhydria has been studied by Dobson by fractional meal tests to determine the effect of giving acid and pepsin. These substances have been administered, combined and separately, in varied dosage, single or fractional, and at different times in relation to meals. A few days after the administration had been begun there were evidences that secretion had increased, and after thirteen days free hydrochloric acid and pepsin in fair concentration were found in the stomach spontaneously after a test meal The dosage necessary to maintain free acid in normal concentration in the stomach throughout digestion was dependent on the composition of the meal, especially from the standpoint of protein For a simple carbohydrate test meal, free acidity could be maintained in normal concentration with adequate dosage at sufficiently frequent intervals during digestion. There was evidence suggesting that free hydrochloric acid not only regulated the activity of pepsin but also influenced its secretion

Comparative Study of Ephedrine and Epinephrine.—Nadler found that epinephrine is about twenty times as effective as ephedrine in antagonizing the action of the extracts of the parathyroid and the anterior pituitary gland, and twice as effective in antagonizing the action of the extract of posterior lobe of the pituitary gland Ephedrine is almost ten times more effective than epinephrine in antagonizing barium chloride. On the basis of the minimum effective dose, epinephrine is two and one-half times as efficient as ephedrine

42: 1031 1096 (April 15) 1927

*Intradermal Smallpox Vaccination J N Force, Berkeley, Calif —p 1031
*Arsphenamine Sodium Thiosulphate Treatment of Experimental Syphilis C Voegtlin and H A Dyer, Washington, D C —p 1045

Intradermal Smallpox Vaccination.—The literature on the administrative use of the immediate reaction of immunity following smallpox vaccination is reviewed by Force, the causes of failure to obtain this reaction are discussed, and the immediate reaction of immunity following intradermal smallpox vaccination, and the technic of this vaccination, are described It is stated that in order for the vaccine to reproduce it must come in contact with the derma, and a satisfactory scarification should completely remove the epidermis but should not draw blood If the epidermis is completely removed there will be a small, brown, circular scab on the sacrified spot twenty-four hours later If the scarification site presents a pinkish or rose colored spot at this time, the epidermis has not been punctured The vaccine should be rubbed on the exposed derma, not simply dropped on it

Treatment of Experimental Syphilis—In view of the well established therapeutic action of thiosulphate in arsphenamine intoxication, Voegtlin and Dyer experimented to determine whether this drug might not be of value in preventing those toxic manifestations which would otherwise occur as a result of more intensive treatment with the arsphenamines Large doses of sodium thiosulphate did not decrease the trypanocidal efficiency of arsphenamine, neoarsphenamine or sulpharsphenamine, nor did they exert a deleterious effect on the spirocheticidal action of sulpharsphenamine Sodium thiosulphate injected intravenously into rats and rabbits was found to have a very low toxicity

Surgery, Gynecology and Obstetrics, Chicago

*Baldwin Operation for Formation of Artificial Vagina. S. Judin, Serpouhoff, Russia.—p. 530.
*Technic of Open Reduction of Fractures. M. Kirschner, Koenigsberg, Germany.—p. 541.
Obstetric Paralysis. J. W. Sever, Boston —p. 547.
*Correcting Complete Inversion of Vagina With or Without Prolapse. N. F. Miller, Ann Arbor, Mich.—p. 550.
*Carcinoma of Rectum and Rectosigmoid: Choice of Operation. L. P. Bell, Woodland, Calif.—p. 556.
Recto-Abdominal Maneuver for Determining Engagability of Fetal Head. E. D. Resnik, New York.—p. 563.

Tendon Transplantation.—In all tendon transplantations, Lange uses a silk sinew made out of four or eight threads of Turner silk, number 6 or number 12. The silk is sterilized for fifteen minutes immediately before the operation in a solution of mercuric oxycyanide. In only 3 per cent of the first 850 operations was a failure recorded. In cases of gluteal muscle and the latissimus dorsi, Lange makes use of the erector spinae as a substitute for the gluteal muscles.

Results of Cholecystostomy.—Spurling and Whitaker conclude that the drainage of a diseased gallbladder, with the expectation that it will regain its normal function, is not only a futile procedure but one that endangers the future health of the patient.

Operation to Prevent Recurrent Shoulder Dislocation.—To prevent slipping forward of the humerus, Speed drills a hole about 1 inch deep diagonally into the neck of the scapula. Into this is inserted a bone transplant removed from the anterior surface of the tibia. The transplant is driven home, and about three-fourths inch is left projecting anteriorly and obliquely across the lower anterior margin of the shoulder joint. This does not in any way interfere with normal range of shoulder joint motion, but it does prevent the head of the humerus from slipping out forward into anterior and habitual dislocation.

Splanchnic Anesthesia.—The advantages of splanchnic anesthesia over general anesthesia and paravertebral block in well selected cases are stressed by de Takats. The terms posterior and anterior splanchnic anesthesia are recommended to take the place of the terms used by various authors. Block of the splanchnic nerves on both sides results in an anesthesia of the upper abdominal organs. The lower abdomen can be anesthetized by adding to the splanchnic block the anesthesia of the lumbar rami communicantes.

Treatment of Fracture of Femoral Neck.—Instead of encasing the pelvis and lower extremities in a plaster of paris cast, Wilkie effects abduction by means of an apparatus applied to the lower legs with intervening rods.

Formation of Artificial Vagina.—Judin reports six cases in which the Baldwin operation yielded excellent results. All the operations were done under spinal anesthesia.

Open Reduction of Fracture.—Kirschner describes his method of operating in detail. He disinfects the skin with tincture of tannin (acidi tannici, 7.5 Gm.; spiritus vini, 100 cc., and a few grains of fuchsin). Perfect asepsis and complete immobilization of fragments are the results stressed.

Correcting Complete Inversion of Vagina.—A functional vagina with normal length and direction is produced by Miller by means of two "lifting" sutures attached to the sacro-uterine ligaments. It offers a method of supporting the vaginal apex following vaginal panhysterectomy for complete prolapse.

Operation for Carcinoma of Rectum.—In Bell's opinion, the two-stage abdominoperineal operation is the method of choice when the grade of malignancy is high, or when the physical condition of the patient is such that there is no appreciable operative risk.

Labor Retarded by Hydrocephalus Terminated by Draining Spina Bifida. R. G. Bingham.—p. 616.

Cholecystography.—Experience with 125 cases has convinced Mather and Williams that cholecystography by the oral method is easier than the intravenous so far as the preliminaries are concerned, and yields equally satisfactory results from a radiographic point of view. The proceeding is devoid of risk, and the toxic effects are practically negligible. The surgical observations confirmed the roentgen-ray diagnosis in 94.3 per cent of the cases.

Recovery from Epidemic Encephalitis.—In 173 cases reviewed by Robb, twenty-one patients died in the acute stage; 152 recovered from the acute attack. Of 141 patients examined, two and one-half years later, only thirteen were apparently well. All the rest showed some evidence of disease. Eighty-three patients showed parkinsonism; eighty-four were totally incapacitated, and twenty-nine were partially incapacitated.

Melioidosis in China.—A case of the septicemic form of melioidosis is recorded by Pons and Advier from Cochin, China, and certain new biologic characters of the causative agent, *B. whitmori*, are described. An animal origin of the infection in this case is considered probable.

Melioidosis: Bacillus of Whitmore.—The biologic characters, and pathologic effects in animal inoculation, of a strain of *B. whitmori* from Saigon are described by Stanton and Fletcher. It is the most virulent strain of the organism from a human source that has so far been encountered. The case from which the organism was recovered was an example of the septicemic form of melioidosis.

Prevention of Pneumonia Mortality in Children.—Woods concludes that the pneumonia mortality of young childhood is largely preventable, and that there is some, perhaps a large element, of preventability in the mortality from pneumonia of adults between 45 and 64, a time of life when, as is well known, there are gross differences between the rates of mortality in different parts of the country.

Iodine Content of Foods.—A comparative study made by Hercus and Roberts of the iodine content of foodstuffs from goitrous and nongoitrous districts established the fact that the soil iodine is accurately reflected in the food iodine. The iodine content of certain vegetables and animal foods is shown to present a well marked seasonal variation. The maximum iodine content of vegetable matter is reached in the late autumn and winter when growth is at a minimum. In the case of eggs the maximum is reached in the summer, in milk, in the spring. Cooking is shown to have little effect on the reduction of the iodine content of root vegetables, seaweed, fish and bread, but to reduce the content of green vegetables by about two thirds. Commercial salt is shown to be an unreliable source of iodine supply, the majority being practically iodine free. Tobacco smoke is a negligible source of iodine supply. A well defined relationship is shown to exist between goiter incidence and iodine excretion in the urine. The iodine content of human milk in the goitrous woman is shown to be lower than in the nongoitrous, and a relationship is shown to exist between the amount of iodine excreted in the urine and milk during lactation. The flesh of fish is shown to vary in iodine content according to its "iodine environment." The addition of small amounts of potassium iodide to the diet of various animals is shown to increase the iodine content of the thyroid glands and of the food products.

Toxin of Scarlet Fever Streptococcus.—Ninety-eight strains of hemolytic streptococci isolated by McLachlan from scarlet fever cases have been found to produce a toxic principle which in high dilutions is capable of evoking a cutaneous reaction in susceptible persons.

Prevention of Colds by Vaccines.—Ferguson et al. are of the opinion that the available evidence suggests very strongly that it is futile to hope for a reduction in the incidence of common colds among the population at large as the result of the prophylactic inoculation of any of the stock vaccines now available.

*Case of Superfetation. J. Riddel.—p. 93.
Combined Scissors and Needle Holder for Operation of Colpoperineorrhaphy. M. McCullagh.—p. 101.

Involution of Uterus Postpartum.—Teacher says that the fourteenth day is roughly the turning point at which building up definitely exceeds retrogression. At from five to six weeks restoration should be fairly complete, but evidence of recent pregnancy may be recognizable for a considerably longer period, even in circumstances most favorable to involution. Such evidence is found in the presence of pigmented phagocytes, and in the remains of the uteroplacental vessels.

Pathology of Fetal Maceration.—Thomson has examined the tissues of twenty-seven macerated fetuses of viable age. She summarizes briefly the work already done in this field; gives a description of the naked eye and microscopic changes occurring in maceration, and discusses the nature of this process.

Indications for Induction of Labor.—The 123 cases of contracted pelvis and the eighty-two cases of postmaturity discussed by Connan and Owen-Jones, in which labor was induced, occurred in more than 8,000 labors. In 63 per cent of the contracted pelvis cases the operation was performed either too early or need not have been performed at all, and in 61 per cent of the postmaturity cases the operation was performed too early. The only indication recognized by them for induction of labor in a case of so-called postmaturity is disproportion between the head of the child and the pelvis of the mother. The children of women whose labor is induced with castor oil, quinine and pituitary extract do not progress as satisfactorily as those in which labor has not been so induced. Induction of labor for postmaturity and for contracted pelvis with quinine was successful only in 66 per cent and 46 per cent, respectively.

Superfetation.—Riddel reports a case in which a diagnosis of missed abortion was made in the fourth month of pregnancy. At the operation, two fetuses were removed from the uterus. The gestation sacs were separate. The first fetus was of the age of 3½ months, complete with placenta, and was macerated. The second was a fetus of the age of 7 weeks, to all appearances healthy and growing. The uterus was not septate, nor was this a twin pregnancy. The larger fetus had been dead for a considerable time, and the smaller was healthy and growing.

*Nature of Vasodilator Constituents of Certain Tissue Extracts. C. H. Best, H. H. Dale, H. W. Dudley and W. V. Thorpe.—p. 397.

Nature of Aqueous Humor.—Evidence is brought forward by Duke-Elder which suggests that the aqueous humor is a dialysate of capillary blood, in that, when this fluid is equilibrated with arterial blood, its refraction, conductivity and sugar content remain practically unaltered, any change which does occur being in the direction of equilibrium with venous blood. The osmotic pressure of the aqueous is the same as that of a dialysate. It is therefore less than that of the blood, the amount depending on the difference in the colloid content of the two fluids.

Influence of Insulin on Mammalian Heart.—Visscher and Müller investigated the effects of preparations of insulin on the mechanical condition of the mammalian heart, in the heart-lung preparation and in the whole animal, and the oxygen consumption of the heart in the heart-lung preparation. In the heart-lung preparation commercial insulin causes a more or less transitory increase of the power of the cardiac fibers, which appears as a decrease in the ventricular volume necessary to do a given amount of work. The effect is identical in normal and diabetic hearts. In the intact animal, normal or diabetic, a rise in arterial blood pressure follows intravenous insulin injections. There is no direct stimulation by insulin of oxidative metabolism in the isolated heart. After adding blood perfused through the pancreas to the heart-lung preparation, insulin has no further effect on the heart.

Effort of Exertion on Uric Acid Excretion.—Experiments done by Garry showed that ordinary muscular exertion increases the excretion of uric acid on the day of work, the increase extending into the two following days. The output of total nitrogen is similarly affected.

Estrin in Placenta.—It is suggested by Parkes and Bellerby that the presence of estrin in the placenta is more easily explained on the ground that the placenta withdraws estrin from the maternal circulation to protect the fetuses from its action, than that the placenta elaborates the hormone.

Extraction of Histamine and Choline in Liver and Lung.—Histamine and choline have been isolated by Best et al. from alcoholic extracts of fresh liver and lung, in quantities sufficient to account for the immediate vasodilator activities of those extracts. Histamine is responsible for the greater part of this activity, and is present in remarkably large amount in the extract from lung. The physiologic significance of its occurrence is discussed.

*Abdominal Pregnancy. J. Silverstone.—p. 653.
*Erythema Nodosum Following Smallpox. W. L. Tullis.—p. 654.

Muscular Mechanism of Respiration.—Briscoe asserts that the question of stretch governs the order in which muscles will contract and the power they will put into that contraction. The diaphragm is almost the only respiratory muscle worth considering in quiet breathing in animals, and remains the most important in man, though in him it has lost some mechanical efficiency through his orthograde habit. Man is forced to compensate for this relative deficiency of the diaphragm by a greater use of other muscles, these other muscles acting either by active contraction or by persistent tonus of a postural type. If exaggerated these actions are not a normal use of muscle but an abnormal overuse, and in consequence a possible source of trouble.

Cause of Cardiac Dyspnea.—The fundamental cause of cardiac dyspnea, Fraser states, is inefficiency of the myocardium. The clinical features and experimental observations on orthopnea, periodic breathing and paroxysmal dyspnea (or cardiac asthma) are compatible with these conceptions of cardiac dyspnea. Dyspnea may be a dangerous reaction, and in certain cases the direct treatment of it by means of morphine is indicated, but full use of this action of morphine cannot be attained until practical methods of administering oxygen are further developed.

Experimental Meningo-Encephalitis of Mumps.—By the intracerebral injection of a bacteria-free filtrate obtained by passing a gargle from an ordinary uncomplicated case of mumps through the Berkefeld filter, Gordon produced definite evidence of encephalitis in the brain of a monkey.

Abdominal Pregnancy.—Silverstone relates the case of a woman who was said to have had a miscarriage. Two days later she experienced a pain in her left side, and felt a lump in this region about the size of an egg. The lump increased in size and the pain became worse. Some slight rigidity was detected in the left iliac region. There was no vaginal discharge, but there was a suspicion of fulness in the left fornix. The diagnosis of ruptured ectopic gestation was made, and an operation was performed. The left tube was found to be ruptured in almost the whole of its length, and was removed. No trace of the fetus was found. The patient recovered from the operation and did very well for a fortnight. Then suddenly she began to vomit, and it became apparent that she had acute intestinal obstruction. She was operated on again, and a loop of small intestine was found obstructed by a band extending across the brim of the true pelvis. This was divided, and the bowel freed. The left side of the abdomen was about to be examined when a fetus, about 1¾ inches in length, shot out from under the left edge of the wound. A small umbilical cord was present, which led down to a definitely formed placenta. The latter was found to be attached to coils of small intestine, descending colon and omentum.

Erythema Nodosum Following Smallpox.—An unvaccinated girl, aged 6 years, contracted smallpox. In the fourth week, the lesions of erythema nodosum appeared over the extensor aspect of both legs. Careful examination of the child failed to reveal any evidence of rheumatism. The child's general condition appeared good, and there was no sign of either tuberculosis or syphilis. This is the first case of erythema nodosum Tullis has encountered in a series of 1,900 cases of smallpox.

Delivery of Membranes in Normal Labor. F. Keane.—p. 195.

Treatment of Perforating Peptic Ulcer.—Thirty-two cases of perforation of a peptic ulcer are reviewed by Söderlund. In thirty-one of the cases, the perforation took place in a completely free abdominal cavity; in the remaining case, peritonitis was limited to the tract above the transverse colon. Of the thirty-two patients, thirty-one have been dismissed as cured and free of symptoms. Only one patient died. The time between the perforation and the operation was usually short, being, as a rule, only some few hours, and the majority of the patients have been comparatively young; only twelve were 40 years old or upward, but of these one had reached the age of 65, one of 60 and one of 55. The operations in these thirty-two cases were performed by six different surgeons. After the ulcer has been excised, the perforation opening closed and the abdominal cavity irrigated with a solution of warm common salt, a typical Witzel fistula is performed in the front of the stomach. As a rule, the gastrostomy tube can be removed about a week after the operation. The after-treatment is simple. The most important part of it may be said to be morphine injections against pain during the first two or three days, and care that a sufficient quantity of liquid should be administered by rectum or subcutaneously during the period in which the stomach does not empty itself down the intestine.

Etiology of Peptic Ulcer.—Douglas summarizes his views as follows: The gastric mucosa is protected from digestion by its own secretions through a delicately balanced biochemical mechanism, breakdown of which precipitates the formation of "peptic ulcer," and this breakdown is due to a trophoneurosis of toxic origin. The same toxic neurosis, which is probably peripheral, affects also the muscular and glandular mechanisms. The glandular disturbance is usually manifested by hypersecretion, while the muscular disorder shows itself in incoordinate and exaggerated activity, with a high reflex sensitivity to stimulation by free acid. It is obvious, however, that this theory does not negative the possibility of cases occurring with hyposecretion or with muscular atony. The clinical picture presents variations according as to whether the toxic blow falls heavier on one structure or on the other; for instance, if the glands are mostly affected, there may be hypersecretion for some time without ulcer formation; if, on the other hand, the trophic function is profoundly poisoned, the unprotected gastric wall may be digested rapidly and perforate without warning.

Paramyoclonus Multiplex.—On the assumption that there is a hyperovarian or testicular internal secretion in paramyoclonus multiplex, Reid says the treatment resolves itself into ovariotomy complete on one side and partial on the other, or unilateral vasectomy in the male. Paramyoclonus is probably due to a disordered state of the internal secretion of ovary or testis, and is closely related to hysteria, chorea, convulsions, tic and neurasthenia.

Production of Anthrax Antiserum by Simultaneous Injections of Edema Fluid and Anthrax Virus.—Hruska's experiments were as follows: Horses hyperimmunized against anthrax were injected with anthrax virus in one shoulder. The other shoulder was injected with edema fluid formed in cows at the point of inoculation with anthrax vaccine. The area where the edema fluid was injected presented a much more intense reaction than that where the virus was injected. The serum of hyperimmunized horses thus treated possesses a high therapeutic value. It was employed in three stables in which an anthrax epidemic had broken out. The sick animals recovered, and new cases did not occur.

Case of Tortipelvis. J. C. Navarro and A. S. Marotta.—p. 29.

Prognosis of Pseudoleukemic Infantile Anemia.—Beretervide and Bianchi disagree with Roelofs' statement that children with von Jaksch's anemia can be cured with injections of maternal blood and appropriate diet. They are persuaded that the disease is fatal. Alleged cases with recovery presented, they say, nothing else than secondary anemia, probably of syphilitic origin. The diagnosis of von Jaksch's anemia is based essentially on the presence of megaloblasts in the blood. Enlargement of the liver and of the spleen are other important symptoms. Changes in the leukocyte picture may be present or not. Syphilis is a frequent factor in the disease.

Search for Tubercle Bacilli in the Stools, as Diagnostic Method. — Corsonello examined the stools of forty-five patients with pulmonary tuberculosis. In cases in which the tubercle bacillus was found in the sputum, it was almost constant in the feces also. The bacillus was never detected in the stools of healthy persons. It is important to search for tubercle bacilli in the stools in cases of suspected tuberculosis in which expectoration is absent or in which the sputum cannot be obtained, as in infants. Feces containing tubercle bacilli are a possible source of contagion.

*Influence of Venesection on Peak Metabolism. X. Chahovitch.—p. 298.
*Peak Metabolism in Pathologic Conditions. X. Chahovitch.—p. 299.

Impermeability of Placenta for Toxins and Antitoxins.—Nattan-Larrier, Ramon and Grasset inoculated gravid rabbits with tetanus toxin, and then removed the living fetuses by cesarean section. Blood serum from the mother rabbits and from the fetuses was injected into two series of guinea-pigs. The fetal serum did not cause any marked disturbances, while the maternal serum killed the animals. The experiments were repeated with diphtheria toxin. The results were the same. Other gravid rabbits were given tetanus or diphtheria antiserum. A few hours after delivery, blood was withdrawn from the mother rabbits and from the young. Both blood serums were able to neutralize lethal doses of corresponding toxins. While the placenta is permeable for antibodies or antitoxins, the toxins or anatoxins do not pass through it. This impermeability contrasts with the prompt passage of invisible viruses through the placenta.

The Proper Dose of Toxin for the Dick Test.—In Debré and Lamy's opinion, the dose of toxin commonly used for the Dick test (0.1 cc. of a 1:1,000 or 1:2,000 dilution) may be insufficient. Of twenty-three children with scarlet fever, the Dick test, made with the usual dose, had been positive in twenty-one, negative in two. About 377 persons were tested with a single dose and with a double Dick dose. The results disagreed in seven cases; in twenty-one, the reaction was faint with the single dose and intense with the double dose. In these cases, examination of the blood serum revealed that the amount of antitoxin was small, the immunity insignificant. Such persons are susceptible of contracting scarlet fever.

The Alkali Reserve in the Course of Serum Sickness.—Chalier and Thiers' observations were made on ten persons injected with diphtheria or typhoid antiserum. In those who developed phenomena of serum sickness, the alkali reserve tended to become lower. There did not seem to be any relation between the gravity or clinical type of the serum sickness and the variations in the alkali reserve.

Relations Between Insulin, Arterial Tension and Glycemia.—Jung and Auger estimated the changes in the blood pressure and the blood sugar in eighteen dogs after injections of insulin. They conclude that there is not any correlation between the induced hypoglycemia and the induced hypotension. Successive injections of glucose may suppress the hypoglycemia, or even induce hyperglycemia; at the same time, the hypotension may remain unaffected. A minimal blood pressure may be associated with a very high glycemia. The hypotensive action of insulin does not seem to depend on the induced decrease in the blood sugar.

Mechanism of Hyperglycemia Caused by Pilocarpine.—In LeGrand and Bierent's experience injections of pilocarpine nitrate produced in dogs a high hyperglycemia, lasting for about fifty minutes. In suprarenalectomized animals the same injections induced an unappreciable hyperglycemia, which disappeared rapidly. Evidently the suprarenals share in the mechanism of hyperglycemia.

Action of Venesection on Peak Metabolism and on the Metabolic Quotient.—Chahovitch experimented on pigeons. The peak metabolism was measured in the birds before and after venesection. The latter reduced the intensity of the metabolism, as well as the metabolic quotient. Hence, the thermogenetic property was diminished. In further researches, rats with decreased peak metabolism were found to present a pathologic condition characterized by nutritional disturbances and degeneration of organs. The basal metabolism sometimes remained normal in these animals.

*Latent Chronic Prostatitis. J. Perrin.—p. 21.
Cyst of the Prostate. André.—p. 30.
Thrush and Vesical Stone. M. Rafin.—p. 32.

Latent Form of Chronic Prostatitis.—Perrin reports four cases in which chronic inflammation of the prostate was not revealed either by functional symptoms or by urethroscopic examination. In the latent form of prostatitis, the lesions are located chiefly in the interstitial tissue. It happened that this form was observed more frequently than the prostatorrheal form. Slight pain in the perineum or urethra, the appearance of a drop of pus in the urethral orifice, sometimes the presence of orchiepididymitis, suggest the diagnosis. The diagnosis is confirmed only in the course of the treatment. Gonorrhea is the usual cause. The treatment consists in digital massage of the prostate and the vesicles, repeated three times a week. Each sitting lasts five or six minutes; it is preceded by urethrovesical irrigation with an antiseptic solution. The massage is supplemented by electric effluvation on alternate days. An electrode is placed in the rectum. Cure usually follows in three or four weeks. Recurrences do not take place.

Curable Form of Sclerema Neonatorum Marfan and Hallez.—p 32

Pneumococcus Peritonitis in Young Children.—Marfan and Florand describe a case of peritonitis, apparently of tuberculous origin, in a girl, aged 2½ The respiratory signs, the positive tuberculin reaction and the fact that the child had been repeatedly in contact with a tuberculous person tended to sustain the diagnosis Not before a phlegmon appeared in the umbilical region was the real character of the peritonitis established. The phlegmon, which is characteristic for pneumococcus peritonitis, occurs rarely in tuberculous peritonitis The phlegmon developed into an abscess, pneumococci were found in the pus in large amounts Tubercle bacilli were not present. The girl died from complicating perforation of the intestine. The authors believe that roentgen-ray examination would have been a great help in the case A shadow representing an irregularly distended bladder might have suggested the diagnosis of pneumococcus abscess

Pathogenesis and Treatment of Primary Diarrhea in Breast-Fed Infants.—Slobosiano and Munteano advocate the use of adsorbing substances in treatment of primary diarrhea in breast-fed infants The diarrhea may occur from an abnormal amount of lactose in the maternal milk, which is responsible for fermentation and an excessive content of acids in the infant's stools These acids accelerate the intestinal peristalsis. Adsorbing substances neutralize the intestinal acids. They use a mixture containing water 175 Gm, aluminum silicate and animal charcoal or tricalcium phosphate, 10 Gm each, ether 2 Gm and syrup 25 Gm. Two teaspoonfuls of the mixture is given four or five times a day. The intestinal colic disappears soon after the beginning of the treatment, the stools become normal in from three to six days.

Therapeutic Methods in Scabies Veyrières.—p 353

Value of Resorcin Flocculation Test in Tuberculosis.—Goiffon and Prétet employed resorcin in the flocculation test of serums from 200 tuberculous and nontuberculous patients. In the progressive form of tuberculosis, the photometric index of the flocculation was in the zone included between the 15th and 40th degrees After the tuberculous process became stationary or was cured, the photometric index dropped to normal In serofibrinous pleurisy, flocculation of the serum was intense in the beginning of the disease; it became unappreciable after resorption of the fluid. In healthy persons, the reaction was always negative In patients with a nontuberculous disease, the reaction was positive in 9 per cent; this occurred most frequently in those with skin eruptions or with hemorrhages A curve indicating successive changes in the flocculation test may be valuable in the prognosis of tuberculosis

*Roentgenotherapy of Spinal Cord Tumors R Ledoux Lebard and E Piot.—p 465
*Lesions of the Hand from Indelible Pencils. M. Iselin.—p 467.

Roentgen Rays in Treatment of Tumors of the Spinal Cord.—Ledoux-Lebard and Piot emphasize the value of roentgen rays in diagnosis and treatment of tumors of the spinal cord. Roentgen-ray examination preceded by injection of lipiodol, enables one to locate exactly the seat of the tumor; after operation roentgen rays are used to complete the cure. The field of irradiation should exceed the limits of the region of operation From 500 to 1,000 Behnken units of deeply penetrating roentgen rays are applied at each exposure; the exposures are repeated at one or two day intervals for three or four weeks. A second series of exposures may be given after a three months' rest. With this method complications have never been observed. In three patients with sarcoma, lymphosarcoma and glioma, respectively, operation supplemented by roentgenotherapy brought about recovery. In one case, the clinical cure is already of three years' standing. In a fourth case, of inoperable angioma, roentgenotherapy used alone resulted in slight improvement.

Lesions of the Hand from Indelible Pencils.—Iselin treated an ulcer of the forefinger, which followed pricking with an aniline pencil. Pricking with an indelible pencil containing methyl violet produces swelling, with a blue discoloration of the skin. If the dye remains long, necrosis of the tissues necessitating amputation of the finger usually occurs. This chemical necrosis is an aseptic one. On operation all dyed tissues should be thoroughly removed. In the case described, incision of the lesion was followed by an atonic ulcer with a serous discharge. After four exposures to ultraviolet rays the ulcer, which had persisted for two months, was healed

Induced Glycemia in Muscular Atrophy.—In four cases of progressive muscular atrophy, Marañón studied the blood sugar, fasting and half an hour and one hour after peroral administration of 25 Gm. of glucose in 200 cc. of water In all, the sugar metabolism exhibited a prediabetic lack of balance. The extent of the induced hyperglycemia paralleled that of the atrophic process.

Acids and Bases in Diseases of the Thyroid.—Morros found a low alkali reserve in the blood plasma in nine cases of hyperthyroidism. The figures were normal in a case of hypothyroidism. The existing acidosis did not bear any relation to the severity of the clinical condition nor to the basal metabolism. These observations support those of Walinski and Herzfeld and contradict those of de Cires and Silva. Morros plans to try thyroid medication in normal persons to see if the alkali reserve will decrease. Insulin and alkalis are also being tried in his cases of hyperthyroidism.

The Shedding of the Endometrium During Menstruation.—The material studied by Bohnen represents the collection of many years. He found that the individual phenomena varied in different women and in different menstruations in the same woman, but that Schroder's conception of the functionalis (compacta and spongiosa) was confirmed and that menstruation is characterized anatomically by a shedding of the spongy and compact layers of the mucosa down to the basal membrane.

The Myoma Ovary.—Kraul made histologic studies of the ovaries of women with uterine myomas. The changes found corresponded to an intensification and lengthening of functional activity and were attributable to the pelvic hyperemia caused by the myoma. They bore an analogy to the changes present during pregnancy, but were less pronounced. The entire ovary was increased in size and turgescent; the corpora lutea were particularly large and well nourished; the theca interna was hypertrophied; hyaline degeneration was postponed. These changes were found chiefly in connection with submucous or centripetally growing intramural myomas. The effort made by the uterine muscle to expel these growths brings an increased amount of blood to the region and results in pelvic hyperemia.

Intermediary Fat Metabolism and Pregnancy.—Under normal nutritional conditions, there is a slight increase in the acetone bodies in the blood in physiologic pregnancy and it appears that acidosis in pregnancy is largely determined by these substances. Bokelmann and Bock found that in pregnant women, in contradistinction to nonpregnant women, a slight overamount of fat in the diet, the quantity and quality of carbohydrates remaining unchanged, was followed by increase in the acetone body index. They believe that endogenous metabolic processes are responsible

Menstruation and Pregnancy in Kyphoscoliotic Women.—In severe kyphoscoliosis the onset of menstruation is likely to be retarded. Other signs of ovarian hypofunction are also common. The reason may lie in deficient blood supply due to interference with the circulation, caused by the structural deformity, or endocrine disturbances may be responsible for both conditions. The prognosis of pregnancy and labor depends largely on the condition of the lungs and heart. The heart requires special care. The greatest number of deaths take place late in the puerperium and are caused by bronchitis and pneumonia. Klaften analyzes the course of pregnancy and the puerperium in seventy-six cases. In sixty-one delivery took place at term; spontaneous abortion occurred in six, in six further cases pregnancy was interrupted because of decompensation; labor was induced prematurely in three, in one case supravaginal hysterectomy was performed.

The Lactic Acid of the Blood in Pregnancy and Labor.—In forty-eight normal nonpregnant women the average lactic acid content of the blood was found to be 17.3 mg. per hundred cubic centimeters. In fifty examinations of the blood in physiologic pregnancy, from the second month to term, the average was 20.8 mg per hundred cubic centimeters In the first stage of labor, the average in nine cases was 24.3; in four cases in the second stage the average was 44.9, in five cases immediately after the birth of the child, 45.6 mg per hundred cubic centimeters. The increased concentration in pregnancy and labor may mean that oxidation of lactic acid to carbonic acid and water is hindered, or that resynthesis to glycogen is disturbed In a further study Bokelmann found that the lactic acid content of the blood in toxemia of pregnancy was higher than in normal pregnancy; in one case (preeclamptic) it reached 36.1 mg. per hundred cubic centimeters. In manifest eclampsia it was still higher, in one case 68.4, and during labor (first stage) in eclampsia it reached 81.9 mg He lays emphasis on the fact that the high lactic acid concentration in eclampsia is the result, not the cause, of the convulsions and points out that the acetone body acidosis in hyperemesis is likewise a symptomatic acidosis.

Ovarian Hemorrhages.—The ovary has a tendency to bleed, on account of its vascularity and of the opportunity afforded each month with the bursting of the follicle. Hyperemia of the genital organs, whether of physiologic or unphysiologic origin, nutritional disturbances and infections are etiologic factors. The pathologic importance of these hemorrhages depends on their site and extent. Bleeding into the abdominal cavity usually forms a retro-uterine hematoma, but in rare cases it has proved fatal. Berecz examined the ovaries removed at operation in 1,059 cases and found signs of hemorrhage in 108 cases. In only twelve had the bleeding produced symptoms. In these the symptoms resembled those of tumor, extra-uterine pregnancy, appendicitis or torsion of the pedicle of an ovarian cyst. The course may be acute or chronic. Small hemorrhages do not require treatment. Conservative treatment directed toward a supposed inflammatory process often succeeds. Uterine myoma, ovarian tumor or retroflexion of the uterus is usually found with ovarian hemorrhage; if on operation for one of these conditions a hematoma is found, the entire ovary should be removed, since it no longer contains functioning tissue. If in the course of any operation hemorrhagic foci or either cysts or a corpus luteum on the point of rupturing are discovered, they should be excised to avoid hemorrhage, for which the circulatory disturbance consequent on the operation might give the occasion.

Influence of Ovarian Function on Basal Metabolism.—Basal metabolism was not found to be affected by the menstrual cycle in healthy women or by dysmenorrhea. High grade ovarian insufficiency (primary amenorrhea) was accompanied by a decrease of about 10 per cent. The decrease was slight and inconstant in the lower grades of ovarian insufficiency. In about 25 per cent of the cases of hemorrhagic metropathy, the basal metabolism was increased more than 10 per cent. In about 50 per cent of women with myoma, it was increased from 10 to 20 per cent. Castration was followed in 25 per cent of the cases by a distinct decrease, which, however, proved temporary, being present from two to three months after the castration, but disappearing after from six to nine months. In the other cases the rate was normal. In women in the natural menopause, the rate varied in both directions; in some cases it rose as much as 10 per cent. By ovarian preparations it was possible to raise the metabolic rate of castrated women with decreased metabolism to normal, but not above normal. Heyn regards the influence of the ovaries on metabolism as secondary, through its action on thyroid function. In amenorrhea he sees the result of insufficiency of the endocrine system, not of one gland alone.

Anemia of Pregnancy of Pernicious Type.—The differential diagnosis from true pernicious anemia can be made only in the cases that survive and by the fact that they go on, without remissions, to permanent recovery. Leukopenia and glossitis are usually absent. The disease begins in the second half of pregnancy and improvement cannot be looked for while the pregnancy continues. The birth is usually premature, rapid and attended with little loss of blood in the third stage. Pain is slight. These peculiarities are connected with the lack of oxygen in the blood. After the birth the woman becomes suddenly worse and dies or she begins to improve. Improvement may be slow or startlingly rapid. Esch has had six cases with three cures. He does not believe sterilization to be indicated. The question of interrupting the pregnancy must be decided individually for each case: on principle it is justified.

Comparative Studies on the Biology of the Vagina.—Bremicker reviews the literature on the histology and bacteriology of the vagina in various species of mammals and reports his own studies on a large number of animals. The normal vagina of the cow, hog, sheep, guinea-pig and rabbit contains no bacteria. The reaction is in general alkaline. The glycogen metabolism, present in the human species, is absent and the quantity of glucose is small. Attempts at infection in the rabbit, cow and guinea-pig showed that the vagina of these animals possesses the power of self-cleansing in a high degree, but this power is connected with the cells of the lining rather than with the secretion. In the long-tailed monkey the reaction was found to be slightly acid, *Bacillus vaginalis* was present in large numbers, glucose was present in the same quantity as in the human species and glycogen was present in the wall.

Biology and Chemistry of the Vagina in Pregnant Women.—In the vagina of the pregnant woman, Kessler and Uhr found an increased effort at self-cleansing, manifested in high acidification and relatively high glucose values. An acidity represented by p_H 4 in a glucose medium of from 2 to 4.5 per cent guarantees normal biologic conditions, from which a smooth puerperium may be expected.

Biologic Studies of the Vagina in New-Born Infants and in Little Girls.—Kessler and Röhrs found it impossible to obtain dependable material for bacteriologic cultures in the case of living children, but their researches brought out the following facts: for the first few hours after birth the vagina is sterile; thereafter *Bacillus vaginalis* is found and this continues throughout childhood as the sole physiologic micro-organism of the vagina. The biologic conditions in the child's vagina are the same as in the sexually mature woman's. Twelve hours after birth the p_H of the vaginal secretion was 5; during the next few days, from 4 to 4.5; at the end of two weeks from 5 to 6. In the strong, healthy child of a few months old, it is again between 4 and 4.5. The quantity of the secretion and the appearance of the vaginal contents depend on ovarian function, but this is not true of the acidity.

The Fate of the Eclamptic Patient.—Sixty eclamptic patients were examined after an interval of from one to twenty-three years. Twenty-seven did not complain of any symptoms nor present changes attributable to the eclampsia. Thirty made various complaints, in which severe headache and weakness of memory predominated. In three who did not make any complaint, careful examination revealed lesions that were probably the result of the eclampsia. Most of the symptoms were due to injury to the central nervous system. Edema of the legs was present in five cases. Chronic nephritis was not found in any case. There is some evidence that the renal changes, which often persist for a long time after recovery from eclampsia, are nephrotic changes in the tubules. For the high blood pressure frequently seen during the first few years, changes in the blood vessels and vasomotor apparatus are responsible. Since their eclampsia, eight of the women had gone through one normal pregnancy, one had gone through five, one had had two normal pregnancies and six abortions. Four of the women had suffered from edema during pregnancy, two from nephropathies. There was recurrence of eclampsia in four women, in one in each of two later pregnancies; one had had one delivery with eclampsia and one normal delivery. The other two had each had a number of abortions in addition to one delivery with eclampsia.

Biologic Chemistry and Bacteriology of the Vaginal Secretion During Menstruation.—In all of the fifty cases examined by Demme and Baltzer, the acidity of the vaginal secretion underwent a very considerable decrease during menstruation and the vaginal flora deteriorated. The changes persisted for a number of days after the menstruation ceased. These conditions, which represent lowered resistance to pathogenic bacteria, are in accord with the clinical experience of former times and justify the efforts, expressed in the folkways of various races, to protect the menstruating woman from genital contamination.

The Micro-Organisms of the Vagina and the Power of the Latter to Cleanse Itself.—Demme investigated the acid-forming capacity and the acid tolerance of various bacteria. For each variety the limit of tolerance was found to correspond to the maximum production. He gives a table showing the figures for different varieties of the streptococcus, staphylococcus, *Bacillus coli*, *Bacillus vaginalis* and others, and points out that the limit of acid tolerance of all the clinically pathogenic bacteria lies below the average acidity of the normal vaginal secretion of women with healthy genital organs, while the limit of tolerance of the normal inhabitant of the vagina, *Bacillus vaginalis*, is far above it. The capacity of bacteria to form acids and the high acid tolerance of the *Bacillus vaginalis* are the main factors in the self-cleansing power of the vagina. The alkaline secretion of the cervical mucous membrane and the alkaline tissue fluid produced by autolysis of the epithelial cells shed by the vaginal wall are, however, necessary to keep the acidity of the vaginal contents below the point at which the *Bacillus vaginalis* itself would succumb.

Causes of Postoperative and Puerperal Thrombosis and Embolism.—Schumacher analyzes the material of Jaschke's clinic from 1918 to 1925. Conditions favoring general retardation of the circulation, such as cardiovascular disturbances, adiposity and postoperative pulmonary disease, were present in more than half of the cases of postoperative thrombosis of the deep veins of the leg and in 70 per cent of the cases of postoperative embolism. A causal connection between retardation of the blood stream and the occurrence of thrombosis in a varix or a superficial vein of the leg could not be definitely established. In the cases of puerperal thrombosis and embolism, a clinically demonstrable general slowing of the circulation was not frequent, but the conditions favoring retardation of the venous flow in the lower extremities were present in exceptional degree. Vaginal operations showed a special tendency to be followed by embolism. Manual separation of the placenta and tamponade of the uterus favored thrombosis and embolism. Infection was present as a factor in about 63 per cent of both postoperative and puerperal thrombosis of deep veins and in 55 per cent of the cases of postoperative embolism. He believes there is less danger of thrombosis and embolism with spinal than with chloroform or ether anesthesia. Jaschke emphasizes the preponderant rôle of retardation of the blood stream in the causation of thrombosis and embolism and urges that the surgical and obstetric patient be got out of bed early. He recommends active and passive motions of the arms and legs and "respiratory gymnastics," begun on the day of operation and carried out energetically, at least four times a day in the case of the movements and every five or ten minutes, if possible, in the case of the breathing exercises. He warns, however, that if the heart muscle is in bad condition or if the veins are sclerotic, early getting up and too vigorous gymnastics and massage may do harm. He practices systematic digitalization of the heart before operation.

Roentgen-Ray Diagnosis of Pregnancy.—Leiser has found that pregnancy can always be diagnosed with the roentgen ray from the fourteenth week. He discusses the technic and reading of the films. He does not use pneumoperitoneum, because of the risk of setting up uterine contractions.

Experimental Studies on the Etiology of Eclampsia.—In studies which included artificial dilatation of the blood vessels in the region of the uterus in rabbits, Louros and Schmechel believe that they have proved the causal connection between vagotonia and eclampsia. They maintain that the vagal predominance is caused by defective metabolism of proteins, fats and mineral salts and by disturbance of the acid-base equilibrium, and that the ovum itself, together with the woman's constitution, is responsible for the inability of the pregnant woman to maintain metabolic equilibrium. The sperm also seems to have an influence. The therapeutic conclusion is that a superabundance of protein, fat, salt or water is to be avoided in the diet of the pregnant woman.

Survival of Tissue in the Oxygen Chamber.—Liek removed bone and tissue of other organs from rabbits, kept the tissues in oxygen tubes for from one to fourteen days and then implanted them in the omentum or muscle of the donor animal. After a number of days, the animal was killed and the implant examined. Control experiments were made. It was found that many organs beside bone survive explantation for a surprisingly long time, and that the length of survival was increased by exposure to oxygen. This was true of the thyroid, ovary, testis and salivary glands.

Acute Osteomyelitis of Rapidly Fatal Course.—Six cases are described. In all the exciting cause was the staphylococcus pyogenes aureus. A portal of entry in the skin was demonstrable in two cases and Schürer-Waldheim thinks it probable that *Staphylococcus aureus* always enters from the skin, while other micro-organisms favor other portals. The patients were children between 3 and 15 years old. It is particularly pointed out that the earliest death did not occur until seventy-two hours after the onset; therefore, even in fulminant cases there is time for treatment, if the diagnosis is promptly made. Early operation, combined with vaccine treatment, is urged. If the disease is not recognized until late, all treatment is useless. Abscesses and infarcts were found at necropsy in the lungs, heart muscle, liver and kidneys.

The Sex Cycle and Tumors of the Breast.—Moszkowicz studied the tissue changes in the mammary gland that occur in connection with dysfunction of the ovary. The frequency of hyperplasia among these is noticeable. Adenoma, fibroadenoma, cyst-adenoma, etc., arise, he affirms, from disturbed ovarian function. The same cause may be responsible for chronic conditions of irritation, preparing the ground for carcinoma.

Intra-Abdominal Pressure in Relation to Surgery of the Stomach.—Krause studied on the cadaver and on models the conditions governing maintenance of position of the stomach when the body is upright, and made bedside observations on the results of influencing intra-abdominal pressure. The distribution of pressure within the abdominal cavity depends on the mechanical structure of the walls and is governed entirely by the reciprocal relations of the bony skeleton and the flexible wall. It is caused by the elastic tension of the abdominal musculature. Concavity signifies negative pressure, convexity positive pressure. In the subdiaphragmatic space negative pressure is inevitable, in the upright position of the body. Under negative pressure a hollow organ becomes distended and a relatively greater muscular energy is required to contract its walls. Inside the stomach, Krause asserts, a pressure equal to the atmospheric pressure is maintained by active contraction of the stomach wall, but when this wall is relaxed, as in atony, the fundus falls mainly under the influence of negative pressure, and the physiologic fixation of the organ is disturbed. Purging and fasting before operation disturb the intra-abdominal equilibrium and favor negative pressure in the epigastrium. When signs of negative pressure in the upper abdomen, such as sinking in of the epigastrium, appear after operation, the pelvis should be raised. He has seen the symptoms of early postoperative dilatation of the stomach disappear promptly when the patient's pelvis was raised.

Treatment of Postoperative Acidosis.—Beresow, Kuchowarenko and Lifschütz believe that hormones are probably the cause of the temporary disturbance of carbohydrate metabolism which appears after operations, and that the pancreas plays an important part here. Hence, insulin is the appropriate remedy. Preventive treatment was tried in eighteen unselected cases; in four the anesthetic was chloroform, in the others procaine hydrochloride. On the day before the operation 400 cc. of a 5 per cent solution of dextrose and 10 insulin units were injected intravenously. On the day after operation 10 insulin units without dextrose was given to some of the patients. On the other days insulin was given after a glass of sweetened tea. Acetonuria occurred in only one patient, a girl, aged 10, after appendectomy under chloroform. It lasted one day. Therapeutically the treatment was given in four cases of postoperative acidosis with severe acetonuria and in one case of latent acidosis. In these cases all the symptoms subsided on the day of treatment, except that in one the acetonuria continued into the next day. In three cases of surgical shock with high blood sugar, treatment with 20 insulin units and 500 cc. of a 5 per cent dextrose solution was followed by gradual subsidence of symptoms, beginning one half hour after administration; in one case 10 insulin units sufficed. Seven cases of resection of the stomach for cancer (cachexia and high grade anemia) were treated for two or more days before operation with large doses of glucose and daily injections of 10 insulin units. The treatment was continued for four or five days after operation with varying amounts of glucose, and with drop proctoclysis to offset the diuretic action of the insulin. After five days large amounts of glucose were given and the insulin stopped. The results were excellent.

Arginine in Cystinuria.—Hoppe-Seyler isolated arginine from the urine of a patient with cystinuria. He claims that this is the first time that its presence in such a case has been established.

Metabolism of Minerals.—Oehme and Wassermeyer found that the mineral balance depends not only on the added salts, but also on the basic food. Antagonistic actions are found, but absolute amounts of the salts are also important. For instance, on a diet poor in calcium and phosphorus, sodium chloride will cause a negative balance, potassium chloride a retention of these minerals. Sodium chloride may shift the acid-alkali balance toward either side—according to the basic diet. The action of the bicarbonates of sodium and of potassium on the chlorine balance depends on the sodium-potassium ratio of the food.

Diameter of Erythrocytes.—Holler and Kudelka found the average diameter of erythrocytes increased in chronic pancreatitis. It is, as a rule, decreased in diabetes and in disturbances of the thyroid. Only rarely is the diameter increased in the latter group.

Fatty Substances in Benzine Poisoning.—Schustrow and Letawet continued their experiments on the relation of fats and lipoids to benzine poisoning. They conclude that the lowered amount of cholesterol in the blood protects against the action of benzine. They believe that a fatty diet is injurious in such subjects.

Kations and Anions of Serum.—In a large material Jansen and Loew determined the sodium, potassium, calcium, magnesium, chlorine, phosphorus, sulphur and carbon dioxide content of normal serums.

Predisposition and Nutrition.—Saiki reviews the investigations made in his institute by various workers. Strychnine has less effect on avitaminotic (A, B and C) animals than on controls. Renal and biliary calculi form in animals on a diet that does not contain vitamin A and calcium or phosphates. Administration of vitamin A caused disappearance of renal calculi formed under these conditions (roentgen-ray control). Hyperkeratosis, papillomas and cancer develop in white rats on a diet lacking in vitamin A except for small amounts given from time to time to prevent death. Wounds heal quicker under administration of vitamin A. While corned beef does not impair fecundity, canned salmon, given as the only source of protein, results in maldevelopment of offspring. Administration of fried eels causes sterility.

Treatment of Hemorrhoids.—Boas aspirates internal hemorrhoids with Bier's pump and injects from 0.5 to 2 cc. of absolute alcohol into the varicosities. He uses local anesthesia obtained by rectal injection of 50 cc. of a 0.5 per cent solution of procaine hydrochloride with epinephrine. The injected nodes are replaced immediately. With external hemorrhoids the treatment is usually followed by gangrene and the healing takes longer (from eight to ten days). In acute strangulation of hemorrhoids he abstains from treatment. The condition is not dangerous and leads to spontaneous recovery. He does not treat bleeding hemorrhoids in patients with hypertension, because he found that in some the blood pressure increased after the treatment.

Temperature Sense.—Hahn found that the sum of the temperature to which the skin is adapted and of the minimum increase in temperature necessary to produce a sensation of heat is within certain limits a constant (about 34 C.). For instance, a skin adapted to 33.5 C. feels the increase of 0.3 to 0.1 C. When it is adapted to 30 C. it requires 4 C. and at 10 C. fully 24 C. are necessary to produce a sensation of heat. There are some phenomena which might be best explained by the presence of different nervous elements responding to different temperatures.

Dynamic Examination of the Pulse.—Straub discusses critically the underlying principles and the clinical results of Sahli's sphygmobolometry. He refuses to accept any part of it.

Antirachitic Vitamin.—Holtz reports on the teamwork done by Windaus, Pohl and himself in Göttingen, Hess in New York and Rosenheim in London. The substance which absorbs the ultraviolet spectrum and which they identified with the provitamin D was isolated from fungi and called ergosterol. It is a sterol with three double bindings and its absorption spectrum disappears after irradiation. Doses of 0.001 mg. prevented rickets in rats.

Diabetes Refractory to Insulin.—Häusler and Högler made experiments with the blood from a diabetic patient who was not influenced by insulin treatment. While the blood plasma from other diabetic patients inhibits the fixation of dextrose to erythrocytes, no such inhibiting action was present in the blood plasma from this patient. On the other hand, the patient's corpuscles did not accept more dextrose after addition of insulin, until they had been repeatedly washed. They conclude that diabetes of this type is not due to an insufficiency of the islands of the pancreas. It seems that it is due to the inability of tissue cells to respond to the action of insulin.

Acidosis in Vomiting of Pregnancy.—Bokelmann and Bock found from 60 to 100 mg. of acetone bodies per hundred cubic centimeters of blood in light cases of vomiting of pregnancy. In grave cases the concentration rose to from 100 to 400 mg.

Ovarian Grafts and the Reticulo-Endothelial System.—Arnold found complete resorption of ovarian grafts in rabbits. It made no difference whether the animals had been injected previously with trypan blue (to "block" the reticulo-endothelial system) or not.

The Spleen and Water Metabolism.—Asher and Dieticker found increased water metabolism in splenectomized animals. They believe that the spleen checks the hyperactivity of the thyroid.

Treatment of Hay-Fever.—Hamm treats hay-fever with intranasal diathermy.

Action of Anorganic Iodine.—After repeated failures with addition of iodine to the water in which he kept axolotls, Abelin succeeded in obtaining their metamorphosis by intraperitoneal injections of diluted Lugol's solution. He believes that a compound of iodine with the animal's protein is the active substance.

Lactic Acid Fermentation of Tissues.—Loeser confirms Warburg's results. Living young placenta tissue seems to produce lactic acid even under aerobic conditions. He concludes from some of his experiments that it also has this fermentative action in vivo.

Glycocoll Treatment of Hives.—Glaessner had good results in urticaria—especially in cases associated with Quincke's edema—from daily administration of from 5 to 10 Gm. of glycocoll. He believes that it combines with some toxic substances.

Contractions of Ureter.—*Rothmann found that potassium* chloride, choline and epinephrine enhance the contractions of the isolated ureter. Atropine inhibits them to some extent. Calcium chloride inhibits the contractions; pituitary extract at first accelerates, then paralyzes them.

Tattooing of the Cornea with Gold Chloride.—Kottenhahn recommends Knapp's application of a solution of gold chloride to the leukoma of the cornea after abrasion of the superficial epithelium. The method is easier and much safer than tattooing.

Inhibition of Bacteria in the Small Intestine.—Arnold summarizes the work done by himself and his co-workers on the nature of d'Herelle's phenomenon. When the p_H of the duodenal contents is between *5.5 and 6.5, a substance is produced* which inhibits the growth of aerobic bacteria. He finds it probable that this substance is the source of the transmissible autolysis.

Action of Synthalin.—Jansen and Baur found similarities as well as differences between the action of insulin and synthalin. Both preparations lower the amount of sugar in urine and blood as well as that of acetone in the urine. Large doses cause alkalosis. There are, however, differences to the disadvantage of synthalin: the latter does not lower the blood sugar so much; it did not seem to prevent gangrene, and permanent absence of sugar from the urine was not obtained. It increases the respiratory metabolism and lowers the respiratory quotient.

Danger of Combining Scopolamine with Morphine.—Panse reports three cases of grave poisoning with the combination of scopolamine with morphine. One patient received an injection of 0.0005 Gm. of scopolamine hydrobromide and 0.02 Gm. of morphine hydrochloride. In another case, the dose was 0.001 Gm. of scopolamine and 0.03 Gm. of morphine; in the third, 0.0004 Gm. of scopolamine and 0.02 Gm. of morphine. Artificial respiration, continued for hours, resuscitated the patients. He advises using scopolamine alone in excited psychopaths. One milligram does not cause any respiratory or cardiac paralysis.

Nervous Disturbances from Disease of the Skin and Subcutaneous Tissue.—Hartmann believes that there is a widespread disease consisting in a change of the colloid condition of the fluid parts of the skin and subcutaneous tissue into the condition of a gel. Such skin cannot be lifted in a fold, like normal skin, and is sensitive. Sometimes the change is limited to small streaks. These patients have *all the symptoms of neurasthenia, but recover after massage and* application of heat. *Carlsbad treatment is also useful.*

Sex Specificity of Skin.—Herrmann and Schiller injected intracutaneously lipoids obtained from ovaries and testes. They observed after two to four weeks a secondary reaction which occurred in women *after injection of ovarian extracts;* in men, after testicular extracts.

Hemolytic Streptococcus and Scarlet Fever.—Kraus concludes that by using the filtrates on human beings the Dicks found *in an ingenious way the key to the solution of the* scarlet fever problem. He declares that all the postulates are fulfilled for regarding the scarlet fever streptococcus as the agent of scarlet fever and the disease as a specific toxicosis perfectly analogous to diphtheria.

Treatment of Vesical Ureterocele.—Vesical ureteroceles (protrusions of the intramural portion of the ureter into the lumen of the bladder) are found in women almost twice as often as in men. The case here described occurred in a woman, aged 54, and was bilateral. The symptoms, of a year's standing, were paroxymal, stabbing pains in the right lower abdomen and difficulty and burning on urination. The diagnosis was made by the aid of the cystoscope. Martius treated the case successfully by electrocoagulation with a diathermy apparatus. He describes the technic and recommends the procedure in preference to suprapubic cystotomy, unless the protrusion is too large. Anesthesia is not required. He warns against ambulatory treatment, because of the possibility of a temporary hindrance to the passage of urine through the mouth of the ureter treated. For the same reason, both sides should not be treated simultaneously, in case of bilateral vesicoceles.

Electrocoagulation for Small Vesical Fistulas.—For very small fistulas, not surrounded by hard scar tissue, Ottow recommends touching the margins of the fistula with a diathermy sound, introduced into the bladder. The procedure is almost painless. An indwelling catheter should then be inserted and left in position for ten days, to put the bladder at rest and allow the edges of the wound to come together. He had complete success with this method with a fistula of one year's standing, caused through late necrosis in the region of a sutured and healed wound in the bladder wall, inflicted in the course of cesarean section.

*Mechanism of Anaphylactic Shock Evidenced in Isolated Organs. N. N. Sirotinin.—p. 79.
*Blood Calcium in Anaphylactic Shock. P. P. Averyanoff.—p. 90.

Permeability of Cerebral Capillaries for Dyes.—Morgenstern and Biriukoff's experiments consisted in the following: rabbits were trephined and small pieces of celloidin were placed beneath the dura mater. From twelve hours to four days later the animals were injected with trypan blue in the auricular vein. At necropsy, the inflamed part of the brain, adjacent to the celloidin, was found stained. This points to the fact that elective localization of toxins and poisons in certain parts of the nervous system depends not only on the permeability of the plexus but also on that of the cerebral capillaries. Other factors besides inflammation may favor the passage of dyes through the cerebral capillaries.

Mechanism of Anaphylactic Shock Evidenced in Isolated Organs.—Sirotinin isolated the heart and the liver of cats and rabbits immediately after appearance of the induced anaphylactic shock. The property of sugar assimilation in the heart was found not to be altered by the shock. The reaction to antigen was the same in the isolated hearts of sensitized animals as in those of the controls. During the experiments the functioning of the heart was uninterrupted. Hence, the rôle of the heart is not predominant in the pathogenesis of shock. The diastasic and glycogenic properties were preserved in the isolated livers of sensitized animals. The ureagenetic ability was reduced to the same extent as in normal livers in the course of anaphylactic shock. The author sustains Bogomolets' theory that anaphylactic shock is induced by irritation, followed by paralysis of the vegetative nervous system, from inactivation of the complement in the nerve cells.

The Blood Calcium in Anaphylactic Shock.—Averyanoff did not find appreciable changes in the amount of blood calcium in eleven dogs with induced shock. Evidently there is not any connection between anaphylactic phenomena on the part of the sympathetic nervous system and of the muscles, on one side, and ion concentration, on the other side.

Section of the Root of the Trigeminus at the Pons.—In neuralgia of the fifth nerve, secondary to malignant tumor of the nasopharynx, the temporal approach for root section is impracticable, since the growth may involve the ganglion itself or the neighboring structures. For these cases Olivecrona recommends an intradural approach from a suboccipital craniectomy and section of the root at the side of the pons. The operation is technically difficult owing to the depth of the wound and the limited space in which the surgeon must work. To obtain sufficient illumination of the operative field, he recommends a small electric bulb mounted on a thin metal rod, held by an assistant. A suction apparatus is also advisable to keep the field dry. He describes a case, in which operation by the temporal route failed, but a second operation, carried out as described, was successful.

The Roentgen Ray in Examination of Intestinal Intussusception.—Olsson and Pallin report four cases in which opaque enemas were used in the diagnosis of intestinal intussusception in children. In three of the cases reduction was obtained by increasing the pressure of the enema. Anesthesia was not required. The roentgenograms are reproduced.

Vol. 89, No. 2 CHICAGO, ILLINOIS July 9, 1927

ECONOMICS OF PUBLIC HEALTH *

JOHN A. FERRELL, M.D., Dr.P.H.

Director for the United States, International Health Board of the Rockefeller Foundation

NEW YORK

The economics of public health, as I understand the subject, relates to the policy the government has pursued or should follow with reference to the conservation of human health. All important nations are committed to the policy of developing and conserving their natural resources. The citizens who compose the nation represent the most important item in the list of national assets. The protection of their lives and health is regarded as essential to the national welfare. Likewise states, counties and municipalities recognize that the safeguarding of the life and health of the people is a government responsibility. The principle has received universal adoption, but the programs for applying it vary widely as to scope, cost and results.

If the government, in the discharge of its responsibility to society, is to deal intelligently with the problem of human health, it must ascertain the present situation with reference to the amount of sickness—particularly that of a preventable character—its cost, both private and public, what has been done to meet the problem, the amount expended, the results obtained and the indications as to future procedures. Man is a complex organism, and for the economist he is the outstanding variable. Hence the measurement of his health, unlike procedures in mathematics, physics or chemistry, cannot be carried out with a high degree of precision. However, methods for approaching the task have been devised that will give a general idea of the true situation.

COST OF SICKNESS

The cost of sickness in the United States has been variously estimated. Expenditures for the services of physicians and nurses and for hospitals and medicines were estimated for 1921 by Mr. Moore of the Public Health Service as $1,400,000,000, or a per capita of $12.33, and by Dr. Charles H. Herty, of the Chemical Manufacturers Association, for 1925 as $1,015,000,000. Dr. Dublin of the Metropolitan Life Insurance Company has presented similar estimates and reports that 2 per cent of his company's policyholders, and probably a larger percentage of the entire population of the nation, are constantly sick and there is an average loss of wages for each person of seven days in the year. Mr. Homer Folks of New York accepts these estimates and concludes that there is an average per capita expenditure for medical care of $10 a year and a loss of wages because of sickness of $12 per capita a year, or a total of $22.

A study of mortality statistics by Dr. Dublin showed that approximately 33 per cent of deaths are due to causes now generally recognized as preventable. Statisticians have computed the economic loss due to sickness and death sustained by the nation unnecessarily. They estimate the cost of raising an infant to the adult stage when he will become a producer. They then compute his value based on the capital investment that would be represented by his future earnings. The amount of the losses shown by their estimates is stupendous and in comparison the amounts expended by the government specifically for preventing unnecessary sickness and deaths seem insignificant. Time will not permit a full discussion of this aspect of my subject. The amounts involved are probably beyond the comprehension of the average citizen, and no one who is reasonably well informed will question that the loss is extremely large and that the measures for preventing this loss have been wofully inadequate.

EXPENDITURE FOR PROTECTION OF HEALTH

It is probably impracticable to ascertain, with any degree of accuracy, the amount of money now expended in the country for the protection of health. A large sum, of course, is spent privately by individual families for food, clothing, housing and sanitation. To an increasing degree these families arrange with physicians and dentists for advice and treatment before much damage occurs. Industrial corporations are making provision to protect their employees against sickness, exposure and fatigue and are striving to improve environmental sanitation. I have not found estimates as to the amount of the expenditures of this character which directly or indirectly influence health. It is known that they are quite large and are increasing.

Many public expenditures, not specifically for public health, exert a most important influence on health. Public schools, for example, teach the elementary principles of personal hygiene and disease prevention. They attempt to train the students in correct habits of living and teach them how to become productive. It is recognized that a person's capacity to earn should be developed, for the larger his income, the higher will be his standard of living. In turn this should mean better health, and better health should make for greater wealth. Ability to purchase health protection, either from the individual or the community standpoint, is a basic factor in any plan for conserving public health.

Notwithstanding these large expenditures which influence health but are not recorded in health budgets, I shall limit the present discussion primarily to the expenditures by the government specifically for public health. According to official records, the federal government expended in 1923 for public health, through a number of departments, approximately $5,000,000 (table 2), or a per capita of 4.5 cents. According to Mr. Harry H. Moore, whose book shows the use made of the taxpayer's dollar for 1923 and 1924, 6 cents went for certain civil functions, and "of this amount 0.4 of one cent was applied to the promotion of health by all federal departments."

---

* Read before the Conference on Public Health, Chicago, March 25, 1927.

The forty-eight state health departments expended for 1925 approximately $10,145,826, or 9 cents per capita. However, their expenditures for institutions, particularly those for the care of tuberculosis, are not included in these figures because there is a lack of uniformity in the various states in handling this phase of the work. In certain instances, tuberculosis expenditures are under the state health department; in others, they are under special boards. Figure 2 shows, by states, the population, the expenditures by the state health department (exclusive of those for tuberculosis institutions), the per capita state appropriation for the health department, and the per capita income for the state. It will be noted that Delaware, for 1925, heads the list in the per capita expenditures for health. This state spent 32.9 cents and had an average per capita yearly income of $797. Nebraska is at the foot of the list with a per capita expenditure for its health department of only 2.5 cents for 1925. Its per capita income was $491. California and New York show the highest per capita incomes of $1,255 and $1,250, respectively, but in per capita expenditures through their health departments New York takes twelfth place, expending 11.6 cents per capita, and California thirty-first place with an expenditure of 6 cents. These states, as well as several others, such as Ohio, Massachusetts and Illinois, have a number of very large cities which, in addition to contributing toward the state expenditure for health, finance their own health services.

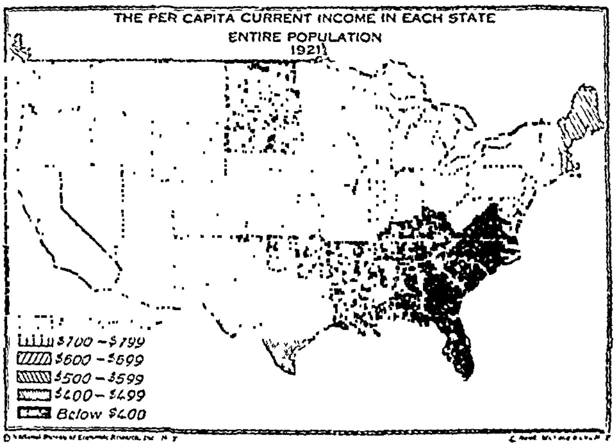

Fig. 1.—Per capita current income in each state, for the entire population in 1921.

Thus, though the state appropriation for health work is contributed by the whole population, its benefits are restricted to a smaller population. Therefore the beneficiaries of the work, although their per capita income is comparatively high, are actually paying much less per capita for health work than the people of many less populous and less wealthy states. In Mississippi and North Carolina there are no large cities, so that the per capita expenditures shown in the table represent, in the main, funds derived from the people served. However, as the negro population is relatively large and the negroes pay a very small percentage of the taxes collected, they benefit out of proportion to the amounts they pay. Even so, the per capita income of both states is relatively low, that for Mississippi being only $252 and that for North Carolina $336, and yet, with a per capita expenditure for the state health department of 16.7 and 15.7 cents, respectively, they take fourth and fifth places in the list of states.

In 1924, 248 cities, having a population of 40,000 or more, or an aggregate population of 39,981,105 inhabitants, spent approximately $34,206,343, or a per capita of 86 per cent. A recent survey[1] of the health department of the hundred largest cities in the United States for the year 1923 contains an analysis of expenditures prepared by Dr. Allen W. Freeman. The average per capita expenditure for health by these cities he gives as 88 cents, which aggregates $28,413,998, but he points out that the budgets are not uniform as to items, as some of them include mosquito control, rodent control, support of hospitals, garbage disposal, plumbing inspection and poor relief. He enumerates twelve items considered essential that are more or less common to all the cities, and for each he gives the actual average cost in cents in one column, and in another the most usual amount expended (table 1). For fifty-three of the 100 cities the per capita expenditures ranged from 50 to 75 cents, and for the entire list the lowest per capita expenditure was 21 cents and the highest, that for Jersey City, was $1.122.

Table 1.—*Per Capita Cost for Health Services of One Hundred Largest Cities of United States for 1923* *

Twelve Essential Items	Average Actual Cost, Cents	Most Usual Cost, Cents

1920	5,985,765			1923	82.10
1924 (budget)	8,737,312				

* Moore, H. H.: Public Health in the United States.
† These items include expenditures only for the U. S. Public Health Service, but they include expenditures for hospitals, immigration inspection, and the like, which are not regarded strictly as a part of a public health program. It has been estimated that about $5,000,000 yearly is now spent by departments of the federal government for activities that are strictly in the public health field.
‡ Bull. 164, U. S. P. H. S.

At the close of 1926 there were 341 full-time county health organizations in thirty-four states. In six of the states, Alabama, California, New Mexico, North Carolina, Ohio and Tennessee, that are widely distributed, there are 439 counties (table 4). "The National Market" of the Crowell Publishing Company lists 40 per cent of these counties as "best,"

---

1. Bull. 164.

25 per cent as "good," 21 per cent as "fair," and 14 per cent as "poor." Fifty-three per cent of the "best" counties and 29 per cent of the "good" counties have full-time health units which spend, on an average, 30 cents per capita. Only 15 per cent of the "fair" counties and 10 per cent of the "poor" ones are organized, but the average per capita expenditures for them were 33 cents and 59 cents, respectively. Expressed in other words, there are 145 counties in these six states which have full-time health organizations, of which 125 are in the "best" and "good" counties, and only twenty in the "fair" and "poor" counties. The counties designated as "best" have a gross income of $12,000,000 or over, which represents approximately a per capita income of $700 or over. The "good" counties have from $5,000,000 to $12,000,000 income, or, roughly, $400 per capita. The "fair" counties have from $2,000,000 to $5,000,000 income, or approximately $250 per capita income. The "poor" counties have a gross income of $2,000,000 or less, which usually represents a per capita income of $200 a year or less. Unfortunately, the large map of the Crowell Publishing Company, showing the counties and the economic status of each, will not be adaptable for publication with this paper. However, the National Bureau of Economic Research issued a map for 1921 which shows the per capita current income for each state. It is smaller, but has suggestive value as to the relative economic situation in the various states (fig. 1).

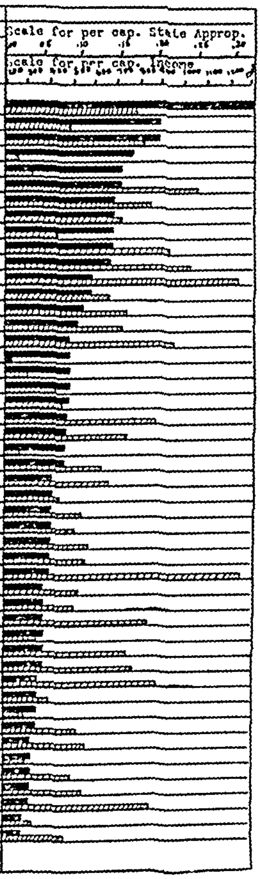

Fig. 2.—State health appropriations in relation to income; per capita basis: solid black, per capita state appropriation (in cents) for health work; shaded area, per capita income (in dollars). 1, amounts exclude appropriations for tuberculosis institutions and the like, but include special revenues and fees allocated to state health department. 2, data from "The National Market," courtesy of the Crowell Publishing Company, New York.

The nation's investment in public health service in relation to its expenditures for other purposes would seem to be exceedingly small. The average amount spent for medicine per person annually has been estimated as $5, of which $3 was for proprietary medicine. The estimated yearly expenditure for cosmetics was $1.25, for tobacco $21, for chewing gum $0.50, and so on. Of course, there is a vast difference between the marketing of such articles for a given amount of money and securing a like sum for public expenditure. However, Mr. H. H. Moore,[2] in connection with an analysis of the expenditures of the funds of 187 cities in 1921, shows that there was spent, per capita, annually, for public education, $10.62; for police and other protection, $3.66; for highways, $3; for fire departments, $2.57; for charities, hospitals and correction, $2.08; for recreational facilities, $0.99, and for the conservation of health, $0.71. The growth in twenty-five years in the expenditures for education has been noteworthy. The claims on the public treasury for health conservation are certainly as basic as those for education. There is no desire, however, to discount the importance of schools. I merely wish to indicate that gradually health service likewise may come to be publicly appreciated to a much greater degree than is the case at present.

A study of the variation in the per capita amounts spent by various states, counties and cities for public health service is interesting. No inflexible rule seems to hold, but, in general, it is found that there is a high degree of correlation between the amount expended and the extent of the recognized health hazard of the community. Communities subjected to immediate danger from bubonic plague, yellow fever, typhoid or malaria will support public health work in the same spirit with which they will support war. When they find their very existence is threatened, they will pay any amount within their grasp to secure protection. Two Southern towns in 1921, each having about 2,000 inhabitants, were suffering terribly from malaria. Experts were obtained to survey the situations. They found that major drainage projects were necessary, and that the cost would be quite high, approximately $16 per capita in one case and $20 in the other. The people had to have protection or abandon their towns. Though the counties in which the towns are located have an annual per capita income of only $168 and $326, respectively, the towns found the means to buy protection from malaria. The results in both cases were gratifying, and subsequently the maintenance cost has been moderate.

Again, certain communities, states or cities have an average or low death rate; that is, they have no more sickness than is regarded as normal. They are proud of their schools, roads and public buildings, but they are already burdened with taxes. In the absence of recognized danger, it is very difficult to induce them to provide for more than a meager health service.

Between these two extremes of attitude most communities are situated. Where economic conditions are good, the standard of intelligence and the per capita income high, the amount of public funds relatively large, and the customary basis is followed in allocating funds to the usual items, a comparatively high per capita expenditure for health is made. In the poor communities the converse holds true. Quite a number of communities are making relatively large appropriations for health purposes which have neither alarming health hazards nor exceptionally favorable economic conditions (fig. 2). The causes for such generous support will vary, but generally it will be found that the community is well educated in public health matters and this in turn generally means that it has enjoyed capable public health leadership.

---

[2] Moore, H. H.: Public Health in the United States.

INCREASING SPAN OF LIFE

Achievements in the prevention of sickness and death have been remarkable. In 1880 the general death rate for the United States Registration area per thousand of population was 20 and in 1922 it was 11.8. Stated in other words, the average span of life in 1900 was 49.2 years and in 1920 it was 55.1 years, an increase of approximately six years. In New York City for the same period, the span increased from 40 years to 55 years. According to Dr. Dublin, the life expectancy of a new-born baby was 49.24 for the United States registration area in 1901 and 57.32 in 1926, a gain of 16 per cent, and the expectancy for New York City for a fifty-year period has increased approximately 60 per cent. He concludes that it is within the range of possibility to lengthen the average span of life from the present 57 or 58 years to 65 years. The tuberculosis death rate of the country has been cut from 180.5 in 1900 to 80.2 in 1924, a reduction well in excess of 50 per cent in twenty-five years. Examples of this character (table 3) could be multiplied.

TABLE 3.—*Reduction in Death Rates*

Year	Death Rates per 100,000 Population in U. S. Registration Area: Tuberculosis of Respiratory System	Typhoid	Diphtheria	Infant Mortality, No. of Deaths Under 1 Year per 1,000 Live Births

1924	80.2	6.7	9.4	70.8

Although it is not possible to evaluate accurately the influences that have produced such results, it is reasonably certain that among contributing factors have been a broader and more accurate knowledge of diseases and of methods for their prevention and cure, a better educated public, better trained physicians, dentists and nurses, more adequately equipped hospitals, larger average earning capacity, higher and more hygienic standards of living, better diet and housing conditions and, emphatically, the work of health agencies, official and voluntary. Although the extent of the contribution to the improved conditions made specifically by the health agencies cannot precisely be determined, it is known that some of the most conspicuous and clear-cut achievements in the public health field were due mainly to the leadership and activities of public health authorities. This certainly would hold true in the practical disappearance of yellow fever, cholera and plague and to a slightly less degree, perhaps, to the extensive control of smallpox, diphtheria, typhoid, malaria and hookworm disease. The definiteness and rapidity with which these diseases have yielded is a tribute to public health leadership and an indication that this leadership should be supported in the numerous public health measures that are recognized as rational, even though the basis for measuring tangible results is not clear-cut.

AN ADEQUATE HEALTH PROGRAM

Methods for the evaluation of expenditures for activities in the public health field, particularly those not promptly reflected by mortality statistics, have been discussed extensively in recent years. A standard of measurement has not yet been devised comparable, from the standpoint of accuracy, with those employed in business enterprises for determining which procedures are fruitful and which wasteful. In a farming project it is possible to ascertain by tests the kind of seed, the amount of cultivation, the kind and amount of fertilizer that, for a given tract of land, will produce the largest yield. In a department store, the management can ascertain accurately the profit or loss from the shoe, clothing or hat division. In a health department it would be desirable similarly to evaluate the expenditures of each division. Unfortunately, the measurement of health is no easy task. Well known authorities are convinced that certain specific activities or services will protect and conserve health, and they have strong evidence in support of their views. The public at large definitely desires and values these services. It is practicable to obtain a financial equivalent for such services. That is to say, activities can be translated into dollars or dollars into service. This approach to the problem of evaluation in the health field is now being employed experimentally in city and county health work, but, since the dollar or the item of service cannot, with precision, be translated in all instances into terms of health conservation, certain questions arise, particularly with reference to the character and scope of the program, which lead to differences of opinion.

When, therefore, a discussion occurs as to what would constitute an adequate public health program, widely ranging views are presented. Practically every one will agree with the theory that a sound health program should apply fully our present knowledge as to the prevention of sickness and death as far as practicable under present economic conditions. Of course, there is a group of diseases about which too little is known to permit the organization of any rational procedures except for research. There is a second group of diseases concerning which basic knowledge is limited. They should be studied with a view to obtaining more knowledge in order that improved measures of control may be devised. There is a third group of diseases for the control of which all essential knowledge is available. Little difference of opinion really exists, however, as to the correct procedure in applying present knowledge.

The main question about which controversy centers is: What part of the program of hygiene and preventive medicine should the physicians, dentists and nurses conduct with their compensation derived directly from the individuals or families immediately concerned, and what part should be carried out by suitably trained personnel employed by the community at public expense? In other words, the bone of contention is the distribution of the work in the field of preventive medicine. The broad-minded, sincere advocate of the cause of health is concerned primarily in getting the work done. He would like to see as much as possible of the task provided for privately between the individual and the practitioner, and the remainder assumed by the community. Of course, it has been argued that the physicians have not, cannot, or will not meet the situation, and unless the community broadens the scope of its health program, great and needless waste of human life will result. Effort should be made to determine the true situation and if the present order with reference to the practice of preventive medicine on a private basis is unsatisfactory, it should be ascertained what assurance can be given that changes will be made so that the community responsibility for controlling disease and conserving health may not be expanded beyond the degree necessary.

DISTRIBUTION OF COST

The economic status of the people in any community has a direct bearing on the whole problem because there is a limit beyond which it is impracticable for the individual to pay or for his community to pay. Where there is a high average of sickness and physical disability, there is likely to be a low average of income. This in turn makes for low standards of living, low productivity, inability of the individual to pay for medical service, or to pay taxes with which to provide service at public expense. Thus in states, cities and counties having a high per capita income (fig. 1) the individual does not need so urgently health facilities financed by the community, and yet it is in such communities that it is practicable, without excessive taxation, to supply such facilities. The same situation applies also to educational, social and recreational facilities. In poor communities the converse situation holds true to a depressing and perplexing degree.

We are confronted, then, with the question not only as to the per capita amount of public funds that should be spent for the conservation of health but also how the cost should be distributed between municipality, county, state and nation. It is perfectly obvious that if one group of communities has a per capita annual income under $200 a year and another group $1,000 or more, there will be a tendency for individual and physician to move from the poor communities to the prosperous ones. If this should proceed far enough, it would result, on the one hand, in the virtual abandonment of extensive rural areas where there now are producers of raw materials and consumers of manufactured products. On the other hand, there would occur ultimately excessive congestion of population in the communities that are now prosperous. Shall rural America be sacrificed to industrial America? From a far-sighted standpoint, is it in the interest of the welfare of the nation, or even of the industrial communities, to permit this to go on until the country may be weakened by the consequences? Should state and nation take steps to correct the trend and equalize facilities and opportunities, particularly with respect to health, before political strength is concentrated in the populous centers of industry? The nation has granted some aid on a population basis in matters of health and roads. There is controversy as to whether or not the policy is sound. Assuming that it may be, it does not follow that the problems we are considering in economics will be equitably solved by appropriations distributed on a population basis. The poor communities which are in greatest need of aid are usually large in area and sparsely settled. A few of the states in the field of education have adopted the policy that the child belongs to the state and it is the state's responsibility to see that every child, regardless of location, enjoys a chance to obtain an education, at least up to a minimum standard. Let us assume that a minimum standard of health service should be adopted with the idea that no community, however remote or sparsely settled, should have less than the standard. It would be found that if the individuals of poor communities should attempt to support their health work by taxation in accordance with their ability, based either on a fixed percentage of their income or on a fixed per capita basis (which would, of course, involve greater personal sacrifice), the aggregate amount raised would nevertheless be relatively small. It would still be necessary to have a large subvention from the central government—derived, of course, from wealthier communities. Whatever the items of the health program may be, *it will be found that the cost per item, for example*, a visit to a home by a public health nurse in rural and sparsely settled areas, will amount to from

two to five times as much as a similar visit in an urban community.

In a prosperous community having abundant resources, it would seem then that the sane course would be for taxpayer, physician and health worker to come together and work out a basis that will be fair and equitable and yet insure the application of present knowledge to health promotion and disease prevention to the utmost degree possible. If physician and health worker fail to reach terms, the decision as to whom each activity shall be delegated will be made, wisely or otherwise, by the taxpayers.

For the remainder of the country the interested parties must struggle with a difficult problem in economics. The question of cost both for community and for individual presents a serious problem. With the health authorities of such sections the question is not whether $3 or $5 per person each year is too much or too little for the community to spend for health service, but rather how they can manage to obtain enough money from local, central and outside sources to pay for a service representing as little as 50 cents per person annually.

Few, if any, authorities will contend that the present health service, even in the "best" counties, has approached adequacy, but there is satisfaction in knowing that they have something in the way of service. The real concern relates to what can be done for the 1,000 to 1,500 counties classed as "fair" or "poor." Must the people move to more prosperous sections and abandon these counties, or can they be aided until they may be able to assume the cost of essential health service?

PROGRESS IN THE WORK OF OFFICIAL HEALTH AGENCIES

Notwithstanding the fact that many difficult problems in the field of public health are awaiting solution, it is gratifying to know that during recent years remarkable progress in the work of the official health agencies has occurred. The appropriation of the federal health service was increased from $2,799,000 in 1915 to approximately $8,000,000 in 1924. The combined appropriations of the state health departments were increased from $4,500,000 in 1914 to more than $12,000,000 in 1925. Those for the 100 largest cities increased in the four-year period from 1919, when the per capita appropriation for health was 63 cents, to 83 cents in 1923 (table 2). Since 1915, when there were practically no full-time county health organizations, there were developed, before the close of 1926, more than 330 full-time county health organizations. In all the health organizations, central and local, a better balanced program has been evolved. Provision has been made for all the essential branches of service. Better qualified personnel has been employed. The terms of employment as to salary and tenure of office have shown consistent improvement. Public confidence in the health organizations and their possibilities for rendering indispensable service has been established to an increasing degree. The best type of young men and young women is being attracted to this field of service. These remarkable developments in so short a time should be a source of gratification to those who have supplied the leadership, and should afford encouragement to hope for even greater achievements in the future.

61 Broadway.

RELATION OF VOLUNTARY HEALTH AGENCY TO PHYSICIANS AND HEALTH DEPARTMENTS *

LINSLY R. WILLIAMS, M.D.
NEW YORK

The term "public health" has been somewhat loosely applied to everything which has to do with keeping people well, preventing disease and caring for the sick. Although care of the sick is not considered as a health activity, activities organized for the prevention of disease grow out of the movement for the care of the sick.

The care of the sick was carried on by religious orders during the middle ages and later by private organizations, particularly in England. The colonies and the United States followed the English tradition in organizing private hospitals and later dispensaries for the care of the sick. There were relatively few efforts made by governmental authority in this country for the care of the sick until the middle of the last century. Health departments were organized primarily for the suppression of epidemics; and as the knowledge of disease became more definite, their efforts were also directed to the prevention of other diseases which were known to be noncommunicable.

Hospitals and dispensaries, having begun as institutions for administering medical relief, that is, in caring for the sick, started to expand their work at the end of the last century to the prevention of disease, primarily in the field of tuberculosis. The antituberculosis movement took on more active work at the beginning of this century and has continuously expanded, so that an association exists in every state for the prevention of tuberculosis.

Although there were several voluntary agencies interested in health work, these antituberculosis societies were the first that formulated a definite policy which has been adopted with various modifications by voluntary health agencies interested in the prevention of other diseases. The voluntary health agencies have not formulated a definite policy that is the same throughout the country, yet there are certain similarities which may be expressed as follows: In general, they conceive of their function as being one of investigation, the inauguration of a new activity, the demonstration of its usefulness, transferring the activity to the official agency or discontinuing it. In certain places where the governmental authorities have not made any provision for the care of the sick, the voluntary agencies have carried on a continued activity for the care and relief of the sick poor.

These principles immediately bring up the age-long conflict in regard to the government—whether there should be a great deal of government and the state should do everything or whether the individual should be left to help himself or whether a voluntary group should undertake to secure funds which are contributed in addition to taxation for the carrying on of a special activity.

As tuberculosis work is perhaps the best known, this will be taken as an example. A voluntary health agency organized for the purpose of assisting in the prevention of tuberculosis desires aid in the situation, and its first problem is to determine how many cases of tuberculosis

---

* Read before the Conference on Public Health, Chicago, March 24, 1927.

there are in the community. This is the period of investigation. This study is known as a tuberculosis survey and should be made with the knowledge and assent of the health authorities. The survey is usually made by a nurse or social worker consulting hospital and dispensary records and visiting the poor farm and the physicians practicing in the community; the individual data giving names and addresses of patients with tuberculosis is not divulged. It is usually found as a result of such surveys that there is a far larger amount of tuberculosis in the community than is suspected by the physicians or health authorities.

It is then suggested, perhaps by the voluntary health agency, that the official health authority should create a local dispensary for tuberculosis or a special class for tuberculosis in the existing outpatient department of a hospital, or that a special hospital should be created in the county for tuberculosis or a special pavilion for tuberculosis should be established in connection with the municipal hospital. Whichever of these activities is agreed on is recommended to the local board of health, community council or county board with the usual reply that funds are not available and it is not necessary, that the people won't stand for it, etc. The voluntary agency then determines perhaps to establish a dispensary in the community, and its organization is worked out with the knowledge and advice of the health officer and is maintained for several years.

During this period, it is found that a number of cases need institutional care and no place is available for them. An effort is then made to transfer the maintenance of the dispensary to the local health department and very commonly with success; and as it has been shown that hospital beds are needed, another effort is made to bring about the creation of a special tuberculosis sanatorium or pavilion at the general hospital. This work may be called the period of inaugurating an activity and a demonstration of need.

During this period, the relationships between the health department, the voluntary agency and the medical profession have pushed themselves into the foreground because the health department has insisted on certain regulations for the administration of the dispensary, a private agency, and the local medical society has demanded certain privileges in regard to work in the dispensary or exacted certain conditions in regard to the payment of the dispensary physician and his method of appointment. Let us assume for the moment that the tuberculosis dispensary has been taken over by the health department and the local tuberculosis hospital established, and the voluntary agency has made a study of the relation of tuberculosis to children and has finally concluded that it may with profit to the community direct its efforts to keeping well babies well, this being determined on the theory that if children do not become ill they are less liable to develop tuberculosis. Consequently, the voluntary association organizes a child welfare station for children under school age.

Here again, a number of new questions are brought up in regard to the management of the child health station. There are certain differences between the problems arising in regard to the maintenance of the tuberculosis dispensary and the child welfare station. Tuberculosis is a communicable disease, and any patient believing that he has the disease should have the right to go to a dispensary for an examination and diagnosis, irrespective of his financial status. There is no valid objection to this procedure, although it has been contested by county medical societies. The child health station, however, is primarily an institution for education and not for treatment. It is supposed to examine children, weigh them, and advise the mother how to keep them well.

What parents should be permitted to bring their children to such a center? It is my own belief that parents should be permitted to bring their children for examination and diagnosis, irrespective of financial status, in the same manner as in the tuberculosis dispensary; but this point of view is highly contested by many members of the medical societies on the ground that this will pauperize the family and that such parents should go direct to their physician. The appointment of the physician also creates a difficulty in both instances. The institution or organization that has created the tuberculosis dispensary or the child health station has the responsibility of maintaining the medical efficiency of its work; and as it employs the physician in charge and presumably pays him for his services, it is incumbent on the organization to have the final authority in nominating the physician. On the other hand, many jealousies arise on the part of certain members of the local medical society who criticize the physician in charge on the ground that he is not a specialist, that he is not competent, that he is using the dispensary or child welfare station for advertising, that he is building up his practice by asking patients to come to his office instead of to the dispensary, and so on. The local society may endeavor to secure either the direct appointment of the physician in charge, the rotation in office of the physicians in charge, the appointment of a full-time physician who shall not engage in practice, and the rigid examination of all patients as to their capacity to pay, or that no patients shall be admitted to the dispensary or station except on the recommendation of their physician.

There are two essential difficulties which must be met in the future:

1. The health department and the voluntary agency desire to see diagnostic facilities and adequate medical care provided for every individual in the community. Theoretically, the private practitioner has a similar desire, but feels that every one in the community should have his own private physician. The health department and the voluntary agency advertise their clinics and health stations and do everything in their power to increase their trade. The private physician, on the other hand, may do nothing but wait until the patient calls.

2. The health department and the voluntary agency desire to show in their annual reports the largest number of new applicants and total visits possible, irrespective of financial status of their clients. On the other hand, the private practitioner feels very strongly that neither the governmental authority nor the voluntary agency should give diagnostic service or medical care to those who can afford to pay a private physician, and with certain modifications this is evidently a just point of view. However, there are many people who could afford to pay a modest fee but who cannot be persuaded to go to see a private physician when they or their children seem to be perfectly well, but who might be persuaded to go to a clinic for examination and diagnosis if they knew that no fee would be exacted.

There are also differences between the point of view of the voluntary agency and that of the health department. The health officials are embarrassed at times by the activities of the voluntary agency, and there are two chief reasons:

1. The voluntary agency frequently employs a publicity agent and is able to secure more notices in the press than does the health department, and it not uncommonly gives the impression that it is doing more work than the health department. The voluntary agency has been known at times to be confused in the minds of the public with the health department. There are also times when the policy of the health department is not agreed to by the voluntary agency, or the activity of the voluntary agency may not be approved of by the health department. How can these difficulties be adjusted? They must be settled for the better promotion of public health and for the avoidance of disagreement and for the improvement of the health and medical care of the public and the practice of medicine.

In the autumn of 1925, a physician in New York invited representatives of the voluntary health agency, the state health department, and the state medical society for dinner and an informal conference. At this conference a number of these problems were discussed in considerable detail. This meeting was followed by a series of conferences which brought about a definite realization of the difficulties and finally resulted in the appointment of a committee on public health relations of the state medical society, which has been holding meetings regularly during the present winter with representatives of the voluntary health agency. Although no definite agreement has as yet been reached, both groups are in definite agreement that the health department and voluntary agency must both carry on their activities and that the advice and counsel of the county or local medical society must be sought before a new activity is inaugurated, in particular in regard to matters relating to the appointment and remuneration of physicians. This seems to be the most profitable method of securing progress—conference and agreement, and if not complete agreement, compromise.

2. In the relations between the voluntary health agency and the health department there is a greater difficulty, for the voluntary agency must primarily work in harmony with the health department in order to secure the best results; but occasions do arise when a large number of prominent physicians and health workers and others are in agreement that a definite step in advance should be taken by the health department or a marked change in method of administration of a particular health department activity. In instances of this kind there are health officials who believe that no matter what the health officer desires to do he should be supported.

On the other hand, the voluntary health agency believes that it has the right as a group of citizens definitely to criticize and oppose a policy, plan or method of a governmental official. The latter question can never be solved completely, but many disagreements could be avoided by more frequent conference between the interested parties, by the health department seeking the cooperation and support of the voluntary health agency, and by the latter taking counsel with the health officer and advising him of its plans.

REPORT ON THREE HUNDRED THOUSAND KAHN TESTS *

R. L. KAHN, D.Sc.
PEARL L. KENDRICK, M.S.
AND
J. L. LANDAU
LANSING, MICH.

The first report on the Kahn precipitation test appeared early in 1922.[1] By July of that year, more than 15,000 comparative Wassermann and Kahn tests had been completed in the laboratories of the Michigan Department of Health. The observations indicated that to report both tests to Michigan physicians would give them more dependable results than the Wassermann test alone. Accordingly, July 1, 1922, the Michigan Department of Health began to report the Kahn test in addition to the Wassermann on all blood specimens received in the laboratories for the serum diagnosis of syphilis.[2]

By the latter part of 1923, the Kahn test had become improved and standardized.[3] The necessity for incubation had been eliminated, making it possible to read the results of the test within a few minutes after mixing serum with antigen. The preparation and standardization of antigen had been rendered quantitative, assuring a high degree of constancy of results with the test in the hands of different workers. And what is of the greatest importance, the test had been found highly specific for syphilis and in some respects more reliable than the Wassermann test. In addition to the routine test with serum, the test had been applied to the examination of spinal fluids, a procedure had been developed for the quantitative determination of the syphilitic reacting substances in serum, and a presumptive procedure evolved as a check on the routine test and for the detection of minute amounts of reacting substances.[4]

By October, 1925, there was a comparative record of Kahn and Wassermann tests in more than 174,000 serums in the Michigan Department of Health laboratories. Careful study and evaluation of results in this large number of examinations led the commissioner of health and the laboratory director to abandon the Wassermann test and to make the Kahn test the official procedure for the laboratory diagnosis of syphilis.[5] This, we believe, is the first time a public health laboratory had used alone any serum test for syphilis other than the Wassermann. This paper presents a summary of the data on the two tests up to the time of the abandonment of the Wassermann test, and discusses the experience of more than a year and a half with the Kahn test alone.

COMPARATIVE KAHN AND WASSERMANN TESTS

Results with 174,580 Serums.—From November, 1921, to Oct. 15, 1925, a total of 174,580 comparative Kahn and Wassermann tests were performed. The earlier procedure of the Kahn test was used in 43,000 of these tests, and the present standard routine test in the remaining 131,000. The results are summarized in table 1.

5. Olin, R. M.: Wassermann Test to Be Replaced by Kahn Precipitation Test for Routine Specimens in the Laboratory of the Michigan Department of Health, J. Michigan M. S. 14: 541, 1925.

Considering only the results with the present Kahn procedure, it is found that in 127,304 examinations the two methods checked completely; in 3,438 examinations there was relative agreement and in 808 examinations there was no agreement. Of this last number, sixty-seven (8.3 per cent) specimens were positive in the Wassermann and negative in the Kahn test, while 741 (91.7 per cent) were positive in the Kahn and negative in the Wassermann. The histories on the blanks accompanying the specimens indicate that the larger percentage of these 808 specimens were from syphilitic patients under treatment.

The tendency for stronger Kahn than Wassermann reactions is also shown in the 3,438 examinations giving relative agreement. Of this number, 1,045 specimens were positive in the Kahn and doubtful in the Wassermann against eighty-two specimens positive in the Wassermann and doubtful in the Kahn. Further, 1,960 specimens were doubtful in the Kahn and negative in the Wassermann against 351 negative in the Kahn and doubtful in the Wassermann. A large number of these 3,438 specimens also were from treated cases.

Table 1.—*Kahn and Wassermann Tests in 174,580 Serums*

	Kahn		Wassermann		
	Reaction*	Number of Examinations	Positive	Doubtful	Negative
Results based on earlier procedure	Positive	8,120	7,549	395	176
	Doubtful	2,606	143	1,629	834
	Negative	32,304	173	816	31,315
Results based on present procedure	Positive	24,018	22,262	1,015	741
	Doubtful	4,123	82	2,081	1,960
	Negative	103,379	67	351	102,961

Per Cent Agreement Between Kahn and Wassermann

	Total Examinations	Absolute† Agreement, per Cent	Relative‡ Agreement, per Cent	No Agreement, per Cent§
Earlier procedure ...	43,030	94.17	5.08	0.74
Present procedure ..	131,520	96.77	2.61	0.61

* Positive reaction = ++++, +++ and ++; doubtful = + and ±

† Absolute check = positive, negative or doubtful by both methods

‡ Relative check = positive or negative by one method and doubtful with the other.

§ No check = positive by one method and negative by the other

Results in 8,661 Treated Cases.—In order to get the quantitative picture of the results in serums from treated cases, it was necessary to study the data in a large number of specimens from patients with syphilis known to be under treatment. A tabulation was made over a definite period of time of the results obtained with both tests on all specimens from syphilitic patients definitely designated on the history blanks as under treatment. A record of 8,661 examinations was obtained from July 1, 1923, to Oct. 15, 1925, and the results are summarized in table 2. Of the 2,934 specimens showing disagreement in results, 2,340 gave stronger Kahn reactions than Wassermann, while 594 gave stronger Wassermann reactions

Results with 1,184 Spinal Fluids.—Recently, Keim and Kahn[6] reported a comparative study of Wassermann and Kahn tests in 1,000 spinal fluids The study included 222 cases of general paralysis, 124 of tabes dorsalis; 387 of the diffuse type of neurosyphilis; 250 cases of syphilis with apparently no neurologic involvement, and seventeen cases that showed central nervous system involvement of a nonsyphilitic nature. The authors concluded that "the Kahn precipitation test compares favorably in specificity and sensitiveness with the Wassermann test."

In addition to these 1,000 cases, in which the Kahn tests were performed in this laboratory, 1,184 spinal fluid examinations are summarized in table 3. Of this number, 471 were positive and 556 were negative with both the Kahn and Wassermann tests Thirty-three fluids were stronger in the Kahn, forty-four stronger in the Wassermann, and eighty were anticomplementary with this method and either positive or negative in the Kahn.

Table 2—*Kahn and Wassermann Tests in 8,661 Treated Cases*

Number of Specimens	Kahn Results	Wassermann Results	Number of Specimens	Kahn Results	Wassermann Results
Kahn and Wassermann Results Identical (5,727)					
2,155	++++	++++	184	+	+
242	+++	+++	114	±	±
251	++	++	2,781	—	—
Wassermann Results Stronger (594)			Kahn Results Stronger (2,340)

COMMENT ON KAHN TESTS WITHOUT WASSERMANNS

From Oct. 15, 1925, when the Michigan Department of Health abandoned the Wassermann test, to April 15, 1927, a total of 125,000 Kahn tests were reported to Michigan physicians;[7] not only have there been no complaints during this time, but considerable satisfaction has been expressed by physicians throughout the state Physicians have been particularly pleased with the increased speed of service. Most specimens are reported between four and eight hours after their receipt in the laboratory, and all within twenty-four hours In an emergency case, such as in a blood transfusion, a Kahn report is made within an hour.

Table 3—*Comparative Results of Kahn and Wassermann Tests with 1,184 Spinal Fluids*

	Number of Specimens	Wassermann Results	Kahn Results
Results same with the two tests	471	Positive	Positive
	556	Negative	Negative
Fluids anticomplementary (A C) in Wassermann	60	A C	Positive
	20	A C	Negative
Results stronger with Kahn test	17	Doubtful	Positive
	8	Negative	Doubtful
	9	Negative	Positive
Results stronger with Wassermann test	17	Positive	Doubtful
	11	Doubtful	Negative
	16	Positive	Negative

The acceptability of the Kahn test is due to several factors The test is highly specific for syphilis; it is relatively free from sources of error; it is not influenced by anticomplementary serums, and its results may be obtained within a short space of time.

---

[6] Keim, H L, and Kahn, R L Clinical Studies on the Kahn Reaction for Syphilis, J A M A 84: 881 (March 21) 1925

[7] This number represents that reported from the Lansing Grand Rapids and Houghton laboratories of the Michigan Department of Health

Since the Michigan Department of Health began using the Kahn test alone, many other institutions have taken the same step. In the tropics and in other parts of the world where climatic, geographic or other conditions make the use of the Wassermann test almost prohibitive because of its employment of unstable reagents and its general complexity, laboratories are instituting the Kahn test because of its comparative simplicity and ready availability.

SUMMARY

Comparative Kahn and Wassermann results with 174,580 serums indicate that the Kahn test is somewhat more sensitive than the Wassermann as it was employed in this laboratory.

Comparative Kahn and Wassermann results in 8,661 cases of syphilis under treatment also indicate greater sensitiveness of the Kahn test.

Similar comparative studies in 1,184 spinal fluids indicate comparable sensitiveness with the two methods, except that the anticomplementary properties of fluids which prevent a reading of the Wassermann do not interfere in any way with the Kahn reaction.

Experience with more than 300,000 Kahn tests reported to physicians indicates that this test is a dependable laboratory method in the diagnosis of syphilis.

SPIROCHETAL JAUNDICE

REPORT OF A CASE *

HARRY H. TOWLER, M.D.
AND
JOHN E. WALKER, M.D.
Majors, Medical Corps, U. S. Army
WASHINGTON, D. C.

In 1914, Inada and Ido [1] demonstrated that a spirochete is the causative agent of the form of infectious jaundice characterized by sudden onset, high fever, muscle pains, renal injury and a tendency to hemorrhage. The condition is frequently referred to as Weil's disease. In Germany, Huebener and Reiter,[2] and Uhlenhuth and Fromme [3] reached the same conclusion, independent of the work of the Japanese investigators. Because of its special morphologic features, a new genus was formed for the organism by Noguchi,[4] and it is now generally known in this country and in England as *Leptospira icterohaemorrhagiae*.

The relation of infectious jaundice, as seen in this country, to spirochetal jaundice, has given rise to considerable discussion. In 1923, Blumer [5] was able to state that spirochetes had not been demonstrated in a single case of jaundice in the United States, and he rightly considered as entirely gratuitous the general assumption that all cases of infectious jaundice were spirochetal in origin. During the past several years, however, evidence has accumulated which seems to indicate that the disease may not be at all infrequent. Altogether, six cases confirmed by laboratory examinations have been reported in North America, five from the United States, and one from Canada. These cases are briefly reviewed:

CASES PREVIOUSLY REPORTED

Case 1.[6]—A woman, working in a laboratory in Albany, N. Y., accidentally pricked her finger with the needle of a syringe containing a culture of *Leptospira icterohaemorrhagiae*, isolated from a rat caught at Albany. The incubation time of the infection was seven days, and the diagnosis was confirmed by guinea-pig inoculation. This case is especially instructive clinically in that jaundice was barely perceptible. The true nature of the disease would never have been suspected except for the history of the needle prick. Zeulzer [7] cites from French and German literature five instances of laboratory infection, two of which ended fatally. Another instance is reported by Adamski [8] in Warsaw.

Case 2.[9]—This case occurred in a man, aged 43, employed in New York state, who slept in a kitchen infested with rats. Clinically, the disease was marked by fever, jaundice, anuria, bloody vomitus, and death in convulsions. Leptospiras were demonstrated at autopsy in sections of the liver and kidney.

Case 3.[10]—In a man aged 51, living in Camden, N. J., occupation not stated, leptospiras were demonstrated by direct dark field examination of the patient's blood on the tenth day of the disease, an unusual observation. The clinical symptoms (fever, chills, prostration, severe bodily pains, muscular tenderness of the calves and intense jaundice), however, agree well with the diagnosis of spirochetal jaundice.

Case 4.[10]—A man, aged 44, occupation not stated, living in a cheap lodging house in Philadelphia, had been drenched in the rain one week previous to the onset of the disease. Leptospiras were demonstrated by inoculation of the urine into a guinea-pig on the eighth day of the disease.

Case 5.[11]—This was a fatal case, occurring in a man, aged 42, employed as a laborer (building excavator) in Philadelphia. The patient was almost afebrile during hospitalization (latter half of disease only). An autopsy was not performed. Leptospiras were demonstrated by direct microscopic examination of the blood on the sixth day of the disease, and by guinea-pig inoculation on the seventh day.

Case 6.[12]—In a man, aged 48, who had been working in a slaughterhouse in Toronto, Canada, leptospiras were found at autopsy, in sections of the kidney.

It is our purpose to report another case, in which the diagnosis was confirmed by guinea-pig inoculation and culture, and to call attention to certain clinical and epidemiologic features of the disease, as compared to other types of infectious jaundice.

REPORT OF CASE

History.—T. R., an Italian, aged 31, admitted to the Walter Reed General Hospital, Dec. 6, 1926, and employed as a salesman in the vegetable and meat section of a market, gave a negative history, except that he had cut his leg with a meat cleaver about three months before admission. He had not been outside the city of Washington for six weeks prior to the onset of the present illness.

The patient was well until Nov. 30, 1926 (taken as the day of onset), when he began to cough. There were no other symptoms until December 2, when he began to feel "chilly," with aching over the entire body, most severe in the legs and back. December 3, he had a severe frontal headache, a slight sore throat, severe backache, and pain and soreness in the chest and abdomen. The cough became slightly productive and "bloody," and his nose bled "most of the time." He was nauseated for four days before admission and vomited several times. He had nocturia and believed that the urine contained blood. He thought that he had had a yellow color for about four days, and felt as if he had a high fever.

Condition on Admission.—The temperature was 98.4, the pulse, 126 and the respirations, 28. There were no visual or auditory disturbances. The pharynx and conjunctivae were markedly injected. Blood pressure was 90 systolic and 60 diastolic. The pulse was irregular. The heart was normal. There were many fine râles over both bases. The spleen was not palpable. The liver extended 2 cm. below the costal margin. Jaundice was marked. The patient looked ill, his face was drawn, he complained bitterly of a severe frontal headache, and was restless. The blood count showed: red blood cells, 3 800 000, white blood cells, 19,000, hemoglobin, 75 per cent, polymorphonuclears, 92 per cent. The urine was bile colored and cloudy, the albumin was double plus, there were many granular casts, and tests were negative for leucine and tyrosine. The Wassermann and Kahn tests were negative. The direct van den Bergh test was positive, prompt and diphasic, the indirect, positive and strong. Urea nitrogen was 62, nonprotein nitrogen, 83 (mg. per hundred cubic centimeters). Blood sugar was 161, and creatinine, 2.

Course in Hospital.—The condition of the patient continued with little change until December 14. His jaundice then became deeper until he was almost of an orange tint. He vomited infrequently but continued to be nauseated. His greatest complaint was headache and general muscular pain. His nose bled repeatedly every day. The bowels became constipated and the stools were of the putty type. Blood and bile were found in the urine every day. The temperature remained below 100 F. this entire period.

December 14, he felt better, was brighter and asked for more to eat. He was having much less muscle pain and was nearly free of headache. The direct van den Bergh test, December 16, gave a diphasic reaction—prompt but clearly diphasic. The indirect test was positive, with 22 van den Bergh units. Nonprotein nitrogen was 29.6, urea nitrogen, 18, sugar 145 (mg. per hundred cubic centimeters). The urine showed a trace of albumin but no casts.

December 21, he complained of feeling weak and of having a slight headache. His temperature rose to 101.4 F. The following day it was 102 and the next day, 103. Except for the feeling of weakness and a slight headache, there was no repetition of the previous symptoms. This condition continued for nine days, sometimes with a temperature as high as 104. On the 30th this became normal and remained normal until his discharge, January 15.

During the attack the patient lost about 40 pounds (18 Kg.). His jaundice cleared very gradually, and a tinge remained in the sclerae at the time of his departure. There was extensive falling out of the hair during convalescence.

Detection and Culture of Causative Organism.—December 7 (the ninth day of the disease), 3 cc. of citrated blood was injected intraperitoneally into each of two white half grown guinea-pigs. The direct examination of this blood with the dark field microscope was negative for leptospiras. Eight days after the injection of the blood both pigs showed marked jaundice, especially evident in the sclerae, the ears and about the genitalia. Direct microscopic examination of the blood of the pigs showed motile leptospiras, about one to every three fields. One pig died on the afternoon of the eighth day and the other on the ninth day. Autopsy showed hemorrhagic areas from 2 to 4 mm. in diameter in the lungs, intense jaundice, and cloudy swelling of the viscera. Motile leptospiras were found in the heart's blood, and in great numbers in emulsions of the liver.

Two drops of heart's blood from one of the pigs was placed in Noguchi's leptospira medium.[13] Four days later microscopic examination of the medium showed growth of the organism in pure culture. Since then, the culture has been carried along without difficulty in successive transfers.

On the twentieth day of the disease, two guinea-pigs were each injected with 3 cc. of blood. Two additional pigs were injected on the twenty-second day of the disease. None of these four pigs developed jaundice or other sign of the disease.

The urinary sediment of the patient was examined twice (the twentieth and thirtieth days of the disease). Leptospiras were *not found*.

GENERAL FEATURES OF THE DISEASE; LABORATORY DIAGNOSIS

The symptoms of the patient seen by us agree closely with the disease as described by Japanese and Europeans. The absence of fever at the beginning of hospitalization is undoubtedly to be explained by the fact that the patient was not under observation during the first several days. Following Inada,[14] the typical case of the disease may for purposes of clinical description be divided into three stages.

Febrile Stage.—From the first to the fifth day. Initial chill usually, high fever; headache; cramping muscular pains, especially of the calves; frequently symptoms simulating meningitis (Zeulzer,[7] Martin and Pettit[15]); marked congestion of the conjunctivae, and albumin, casts and possibly red blood cells in the urine. The blood is always positive on guinea-pig inoculation during the first four days though the chance of demonstrating the organism in this manner diminishes after this time.

Icteric Stage.—From the sixth to the thirteenth day. The symptoms and fever of the first stage decrease. Icterus and a hemorrhagic tendency make their appearance. The hemorrhagic tendency is not so frequent in European cases. There is marked general weakness. Hiccup is frequent. In fatal cases death occurs during this stage, usually with convulsions and other symptoms of uremia.[16] The mortality in Europe varies in different statistics between 5 and 18 per cent. In Japan the mortality is higher: from 11 to 48 per cent.

Convalescent Stage.—From the fourteenth day to recovery. There is a gradual subsidence of the icterus and ordinarily continued improvement until complete recovery. Forty per cent of the cases in Europe and 28 per cent of the cases in Japan show a secondary rise of fever, beginning on about the fifteenth day. This secondary rise lasts from four to twenty days. It is not a relapse in the strict sense, for there is no return of the initial symptoms and the blood remains free of the organisms. Also, it seems that death does not ever occur during this secondary fever.

There are exceptions to this typical clinical picture. Patients admitted to the hospital several days after the onset may show little or no fever.

Further, jaundice is not a constant feature of the disease. This is well illustrated by the laboratory infection reported by Wadsworth.[6] From this standpoint the term leptospirosis icterohaemorrhagica is preferable. Stokes, Ryle and Tytler[17] estimate that jaundice was not present in more than 60 per cent of the leptospiral infections occurring in the British army in Flanders.

Although the clinical diagnosis may be made with a high degree of confidence in many patients, it is evident that many atypical cases may be entirely missed without laboratory examinations. The intraperitoneal injection of guinea-pigs, preferably young white animals, with 2 or 3 cc. of blood early in the course of the disease is the method of choice. They become markedly jaundiced after six to nine days, and leptospiras can be demonstrated in the circulating blood or in the tissues.

---

[13] The following formula was used: Physiologic sodium chloride solution 8 parts, rabbit serum, 1 part, nutrient (2 per cent) agar 1 part, "rabbit hemoglobin," 0.2 part. The "rabbit hemoglobin" was prepared by adding 1 cc. of rabbit's blood to 3 cc. of sterile distilled water.

One gains the impression from Japanese and European authors that it is scarcely worth while to search for the organisms by the direct microscopic examination of the patient's blood, though it is to be noted that in two of the North American cases the diagnosis was promptly made in this manner. In one of them the finding was further controlled by positive animal inoculations. It is possible that concentration methods such as those outlined by Schüffner and Sieburgh [18] may further eliminate delays in diagnoses due to the incubation period in guinea-pigs. Such methods are also rendered desirable by the fact that guinea-pigs vary in their resistance to the organisms.

Later in the disease the organisms appear in the urine, and dark field examination of the centrifugalized sediment offers the best opportunity for demonstrating them. According to Inada,[14] the organisms are found in the urine of practically all patients at about the twentieth day of the disease, most numerous inside of cylindroids. We did not demonstrate the organisms in the urine of our patient, and it is to be regretted that more systematic examinations were not made. Martin and Pettit [15] have not found the organisms so constantly present in the urine as reported by Inada.

EPIDEMIOLOGY

Spirochetal jaundice, as it is occurs in Japan and in Europe, is especially prevalent among rice field workers, miners, sewer workers and ditch diggers, and many cases were recognized among troops occupying trenches in the World War. These occupations all require intimate contact with wet or marshy soil. In a great number of instances reported from England, France, Germany and Holland, the disease developed after swimming in, or falling into, rivers and canals. Butchers and cooks are also recognized as showing a high rate of incidence.

Although the disease may be endemic in certain areas, it occurs principally in sporadic cases, rather than in true epidemic outbreaks. Contact is not usually a means of dissemination, though Lyon and Buchanan [19] observed seven cases in children in which the spread of the disease was best explained on the basis of direct contact. It is to be noted that the American cases so far reported have been sporadic.

Ido, Hoki, Ito and Wani [20] found that a high proportion of wild rats and field mice harbor pathogenic leptospiras. Numerous surveys of rats have been made in practically all parts of the world. The results justify the assumption of the presence of the organisms in an appreciable proportion of rats everywhere. It has generally been supposed that these animals play a large part in the dissemination of the disease among human beings, by contaminating soil, water and food with their excrement. That rats do play a rôle in human infections has been apparently shown by the occurrence of two cases of infection following rat bites.[20]

In recent years interest has been shown in the possible pathogenicity of free-living leptospiras, known to occur widely distributed in nature. As a matter of fact, the organisms were observed in the free-living condition by Wolbach and Binger [21] before it was known that similar organisms were connected with disease. The organisms are present in the water of ditches, ponds and lakes. Hindle [22] cultivated them at will from London tap water, and similar experiments show that they are constantly present in the water supply of Washington. No evidence of pathogenicity has been obtained with the organisms here.

Two instances seem to indicate fairly definitely that these free-living organisms have or may acquire pathogenicity. Buchanan [23] found that leptospiras from a mine induced the typical infection in guinea-pigs, and Uhlenhuth and Zeulzer [24] observed that a water strain became pathogenic after prolonged cultivation in serum.

These observations have reopened the whole question of the epidemiology of spirochetal jaundice. Uhlenhuth and Grossman [25] stress the almost constant association between polluted water and the occurrence of cases in human beings. Rats and man, they believe, acquire the infection from these water or soil sources, although rats do not play any appreciable rôle in the spread of the disease in man. It had previously been demonstrated that pathogenic leptospiras may infect guinea-pigs through the shaven skin, and the skin may be the means of the acquisition of the disease by human beings.

OTHER TYPES OF INFECTIOUS JAUNDICE

With advances in bacteriology and epidemiology, a group of conditions known clinically as infectious jaundice (of unknown etiology) has been gradually reduced. Jaundice due to such conditions as malaria, typhoid, relapsing fever, yellow fever and streptoccal infection has been separated from the general group of "bilious fevers" as they were called in the first half of the nineteenth century and properly classified according to etiology. Spirochetal jaundice (leptospirosis icterohaemorrhagica) represents the latest loss from the general group. It by no means included everything remaining in the group, though this impression might be gained from the almost constant use of the terms spirochetal jaundice, epidemic jaundice, and infectious jaundice as synonyms. As already mentioned, Blumer protested against this assumption in 1923. Garnier and Reilly,[26] and Costa and Troisier [16] have especially attempted to clarify nosology in this field. Most cases of infectious jaundice of unknown etiology fall in one of two general classes:

1. *Catarrhal Jaundice.*—This term is probably not correct anatomically. Garnier and Reilly propose the term "acute afebrile icterus." The disease occurs as sporadic cases. The absence of high fever, prostration and conjunctival congestion separates it clinically from spirochetal jaundice. It appears, however, that there is not a sharp line of demarcation between catarrhal jaundice and mild cases of spirochetal jaundice (Martin and Pettit, Inado).

26. Garnier, M., and Reilly, J.: Essai de classification des ictères infectieux primitifs, Presse méd. **28**: 813 (Nov. 13) 1920.

2. *Epidemic (Nonspirochetal) Jaundice.*—This is the "epidemic and contagious icterus" of Garnier and Reilly. Individual cases are clinically exactly the same as catarrhal jaundice. It is highly contagious, the most notable outbreak in this country consisting of the widespread epidemic reported by Wadsworth[6] and by Williams[27] in New York state during 1921-1922. It is probable that "camp icterus," which has played such a large part in military medicine, is to be classified here rather than as spirochetal jaundice. The 71,000 cases of jaundice occurring among Northern troops in the Civil War are almost always cited in American and European text books as examples of spirochetal jaundice. This is an error, for the individual outbreaks cited in the Medical and Surgical History of the War of the Rebellion[28] were all mild, without fatalities, and usually without fever, very similar to what was observed in the New York epidemic of jaundice.[29]

Troisier and Costa,[16] basing their conclusions on clinical and epidemiologic observations, believe that catarrhal jaundice is only the sporadic form of epidemic (nonspirochetal) jaundice, and they group the two conditions together under the term "ictère commun." Further, as a result of pathologic studies in the same epidemic, they consider that "acute yellow atrophy of the liver" is the severe form of this same "ictère commun." These views agree fairly closely with opinions expressed by Blumer and others.

Troisier,[30] however, later states that there is another form of infectious jaundice of unknown etiology besides "ictère commun." This form is febrile, possibly related to paratyphoid bacilli. Nichols[31] found evidence (agglutinins) of paratyphoid infection in jaundiced American troops returning from Europe. It is apparent that the last word has not been said concerning infectious jaundice of unknown etiology, and the situation is further complicated by the fact that neither the clinical nor the laboratory diagnosis of spirochetal jaundice is on an absolutely certain basis, especially as far as negative results are concerned.

RELATION OF SPIROCHETAL JAUNDICE TO YELLOW FEVER

Noguchi[32] described an organism, *Leptospira icteroides,* similar morphologically to *Leptospira icterohaemorrhagiae,* as the causative agent of yellow fever. Although closely related, Noguchi felt that there were enough immunologic differences between the two organisms to separate them. Recently, Theiler and Sellards[33] have reinvestigated the immunologic reactions of the two organisms and are unable to detect any differences. They state that we are faced with two alternatives, between which they do not attempt to decide: first, that *Leptospira icteroides* has nothing to do with yellow fever; second, that yellow fever and spirochetal jaundice are one and the same disease. However interesting speculation may be in this field, the decision between these alternatives, or modifications of these alternatives, must await the results of further investigations. The clinical similarity between spirochetal jaundice and yellow fever has long been recognized, though ordinarily it is only in the tropics that both conditions have to be considered in differential diagnosis.

SUMMARY

The case seen by us, from which we cultivated *Leptospira icterohaemorrhagiae* on guinea-pig inoculation, is apparently the sixth proved case of spirochetal jaundice to be reported in North America.

As usually observed in this infection, our case was sporadic.

Typical cases of spirochetal jaundice show a fairly definite clinical syndrome, consisting of sudden onset, fever and chills, prostration and severe muscle pains, jaundice appearing the fifth or sixth day. Because of the occurrence of atypical cases, laboratory control of the diagnosis by guinea-pig inoculations (early) or examination of urinary sediment (late) is necessary.

Spirochetal jaundice is probably prevalent in the United States, though it includes only a small proportion of cases classified as infectious jaundice (of unknown etiology) before the discovery of *Leptospira icterohaemorrhagiae.*

A review of the literature indicates that the disease is usually associated with polluted water or soil, possibly being caused by leptospiras living free in nature. It is also possible that the rôle played by rats in the dissemination of the disease has been overemphasized.

28. Medical and Surgical History of the War of the Rebellion, part III, volume I (Medical History), p. 874, Washington, Government Printing Office, 1888.

29. It is also generally the custom to cite the infections mentioned by Larrey (Mémoires de chirurgie militaire et campagnes, volume 2, Paris, Smith, 1812) during Napoleon's Egyptian campaign as probable instances of spirochetal jaundice. It is true that Larrey called attention to the similarity of the symptoms with the symptoms of yellow fever in America. The cases described by him, however, were confined almost entirely to the wounded. The infection developed in the hospital, it seemed to spread by contact, and the severity was directly related to the extent of wound gangrene. These unusual features place the retrospective diagnosis of these cases on an exceedingly frail basis

COMMERCIAL BACILLUS ACIDOPHILUS AND BACILLUS BULGARICUS CULTURES AND PREPARATIONS

BACTERIOLOGIC STATUS *

LAWRENCE H. JAMES, Ph.D.
NEW HAVEN, CONN.

The use of *Bacillus acidophilus* in the treatment of abnormal intestinal conditions has attained marked popularity within the last few years, not alone in scientific circles, but with the layman as well. The demand for methods of administration in which the patient can be relieved from immediate dependence on bacteriologist and laboratory has led to the marketing of various kinds of preparations, liquid, solid and semisolid. It is well known that the life duration of such bacterial "cultures" is short, and that the products may become worthless after a comparatively brief period of time. There are few commodities on the retail market the quality of which is so dependent on scientific control as these preparations. The present survey was undertaken in order to obtain more definite information regarding their purity and viability. Because of the close similarity in their nature and uses, both acidophilus and bulgaricus preparations have been included in the study.

Bass,[1] in a brief survey of solid culture products, reports as follows: "In the instance of tablets, none of those examined were found to contain as many as 1,000 viable bacteria of any kind per tablet." He calculates that if all bacteria present had been *B. acidophilus,* "it would take about 1,000,000,000 tablets to contain as many bacilli as are contained in 1,000 cc. of acidophilus milk."

---

* From the Microbiological Laboratory, Bureau of Chemistry, U. S. Department of Agriculture.

[1] Bass, C C Transformation of the Intestinal Flora, Ann. Clin Med **1:** 25 32 (July) 1922.

Recently, the Council on Pharmacy and Chemistry[2] of the American Medical Association published the answers to questionnaires submitted to seven well known scientists who have studied the problems of *B. acidophilus* therapy. All consultants agreed that there was no evidence of intestinal implantation with *B. acidophilus* by the use of what are classed in this paper as solid or semisolid cultures. One consultant wrote, "Since acidophilus therapy has been proved to be essentially a bacteriologic phenomenon, the necessity for a large number of viable organisms seems to me evident. My personal experience is that when the count drops below 100,000,000 per cubic centimeter the results are not satisfactory."

In general, all these workers agreed to the conclusion that lactobacilline preparations should contain abundant viable organisms true to the species claimed. The way was thus open for a comprehensive survey of those preparations as found on the market during the summer of 1926. The samples used in this study were obtained by buying containers of each product from the retail market, usually found in pharmacies. One hundred and seven samples, of which thirty-four were broth and twenty-eight milk cultures, and thirty-four tablet, three powder and eight semisolid preparations, were collected from twenty-one cities in nine states and in the District of Columbia. Immediately on receipt at the laboratory, the samples were placed in storage at 10 C. to await examination. Liquid cultures consisted of either milk soured by the desired organism or whey suspensions of bacteria. Solid preparations were either tablets or powder in capsules. Semisolid products were solidified agar or petrolatum plus other ingredients in which bacteria had been suspended.

ANALYSIS OF PREPARATIONS

The routine examination adopted was as follows:

1. Liquid (broth or milk) cultures:

(*a*) One cubic centimeter of the culture was inoculated directly into each of two tubes containing 20 cc. of litmus milk. The largest amount of culture inoculated was 1 cc.

(*b*) One cubic centimeter of the culture was added to 9 cc. of sterile water, and 1 cc. of this dilution was inoculated into the first set of plates. Different platings were made in triplicate with dilutions to 1:100,000,000. The largest amount of culture plated was 0.1 cc.

2. Solid (tablet or powder) preparations:

(*a*) Three tablets or the powder from three capsules was dissolved in 30 cc. of sterile water.

(*b*) One cubic centimeter of this dilution was then added to each of two tubes containing 20 cc. of litmus milk. The largest amount of culture inoculated was 0.1 cc.

(*c*) One cubic centimeter of the dilution used in *a* was seeded in the first set of plates. Higher dilutions were then plated. All platings were made in triplicate. The largest amount of culture plated was 0.1 cc.

3. Semisolid or jelly cultures:

(*a*) Cultures liquefying at 40 C. These usually had a consistency resembling that of petrolatum. A sterile glass tube (inverted 10 cc. pipet with full size opening) was thrust to the bottom of the jelly and the subsample thus obtained blown into a sterile tube. The tube and subsample were placed in a 40 C. bath, where the jelly was melted and could be handled with a previously warmed pipet. After thorough mixing, 1 cc. was transferred to 9 cc. of warmed sterile water and vigorously shaken.[3]

(*b*) Cultures not liquefying at 40 C. These consisted of solidified agar in which bacteria were suspended. The agar was molded in cubes, each wrapped separately. One cube being considered as one dose, it was selected as the unit. Each cube was thoroughly ground in a sterile mortar, after which 10 cc. of sterile water was slowly added, with continued grinding until an even suspension was obtained. Sterile dry sand was used when necessary, but sparingly in order to avoid rupturing the bacteria.

* A number preceded by a plus sign indicates the number of days preceding, and a minus sign the number of days following, the expiration date on which the sample was examined. X indicates absence of any time limit.

† Products 1, 2 and 3 are the same in all tables.

The results of the analysis listed in the accompanying tables include only data of primary interest. The results of the inoculations into litmus milk furnish only comparative information and are not included here. All platings for total counts were made in triplicate, two being in whey-galactose agar and the third in plain agar. One set of whey-galactose agar plates was incubated in an atmosphere of 5 per cent carbon dioxide, after the method of Kulp,[4] and the other incubated in the ordinary manner. In most of the samples, if colonies resembling *B. acidophilus* or *B. bulgaricus* appeared, a slightly greater count was obtained with the use of the carbon dioxide than without. As these counts present the commercial product most favorable, the figures obtained from culture in the presence of carbon dioxide are given in the accompanying tables. The platings made with plain agar were intended to show the extent of the presence of organisms other than *B. acidophilus* and *B. bulgaricus.*

---

[2] Council on Pharmacy and Chemistry, Present Status of Bacillus Acidophilus and Bacillus Bulgaricus Therapy, J. A. M. A. 87:172 (July 17) 1926.

[3] The weakness of this method is apparent. In all cases but one in which a reaction in milk was obtained, bacteria were found in the water suspension, and the method is believed to give a fair indication of the bacterial status of the product. In one instance in which a typical B. acidophilus reaction was obtained in milk, colonies closely resembling acidophilus were obtained in the agar plates.

8	Bulgaricus and acidophilus	X	500,000	800,000	Not B acidophilus nor B. bulgaricus

Pure strains of the predominating type of organism were isolated from the agar plates from as many samples as time would permit. Types which were obviously contaminants, such as spreaders, were not isolated. On the other hand, if only one colony suggesting *B. acidophilus* or *B. bulgaricus* appeared on a plate, care was taken to obtain a culture from it. The identification of the organisms obtained has been made by a study of the following characteristics:

1. Colony type in whey-galactose agar.
2. Gram stain and morphology.
3. Reaction in litmus milk.
4. Acidity produced in milk.
5. Fermentation of levulose, maltose and sucrose.

It is recognized that these tests do not furnish positive identification of unknowns of the type considered here. With the possible addition of the medium recommended by Albus and Holm,[5] however, they constitute practically our sole means of differentiation in vitro.

Gram stained preparations were made from young whey-galactose agar colonies. Colony types were studied in plates of whey-galactose agar, which was made according to Rettger and Cheplin.[6] The titration of the acdiity was made in litmus milk and calculated as lactic acid. Kulp and Rettger[7] have shown that differentiation in sugar broths which have been sterilized in the usual manner, i. e., by autoclaving, is only partially reliable, and that the use of test broths wherein the carbohydrate has been sterilized by filtration leads to more clear-cut results. For this reason, solutions of the test sugars were sterilized by being passed through Berkefeld filters and then added to sterile casein-digest broth. The inoculum was obtained by growing the organism in whey-galactose broth, removing by centrifugalization, washing in saline solution, recentrifugalizing, and resuspending in saline solution. As a control on the viability of the inoculum after the foregoing treatment, whey-galactose agar plates were seeded after the inoculation of the sugar broths. Only those organisms

were studied that produced a reaction in litmus milk apparently identical with that of *B. acidophilus* or *B. bulgaricus.*

SUMMARY

In summarizing the results of the survey, several pertinent facts are worthy of mention: 1. The milk cultures showed the highest average counts, the whey cultures next to the highest, and the solid cultures the lowest (omitting the inaccurate results of the semisolid cultures). 2. All samples of one type from any one producer, examined before the expiration date, were more or less similar in quality, regardless of their age. 3. Liquid and solid preparations marketed by the same producer were somewhat similar in quality. 4. Contaminating organisms were more common in solid than in broth or milk cultures. 5. Of thirty-three strains of organisms isolated from cultures claimed to be *B. acidophilus,* nineteen showed a possibility of being that organism and fourteen did not; and of fifteen organisms isolated from preparations claimed to be those of *B. bulgaricus,* ten showed a possibility of being that organism and five did not.

Table 4.—*Results of the Examination of the Semisolid Cultures*

Produced by Manufacturer Number	Organisms Claimed	Age of Product	Bacterial Count per Cc. of Sample		Predominating Organisms Found
			Whey-Galactose Agar	Plain Agar	
1	Acidophilus	+91	8,000	0	Not B. acidophilus
2	Acidophilus	+418	20	0	
	Acidophilus	+416	0	0	
	Acidophilus	+408	0	30	
	Acidophilus	+315	40	0	Probably B. acidophilus
	Acidophilus	+246	160	0	Probably B. acidophilus
	Acidophilus	—1	0	0	
8	Acidophilus	Examined 116 days after issued	35 per block	100 per block	

CONCLUSIONS

Therapeutic claims were disregarded in this survey. Of 107 samples examined, thirteen produced the species claimed on the label in reasonably pure form and in satisfactory number. Of the remaining samples, fifteen were sufficiently pure and presented viable organisms in sufficient number to have possible value. The others were worthless as representing cultures of the species claimed.

There is need of revision of the present methods of marketing acidophilus and bulgaricus cultures and preparations, and of adequate, scientific supervision of the purity and viability of such products.

Human Factor in the Causation of Accidents.—A special personal susceptibility to accident exists, inherent in the individual and differing from one individual to another. A comparatively small number of workers is responsible for an undue proportion of accidents, although all are exposed to the same risk. This small group is also found to have higher invalidity rates, and to pay more visits to the ambulance room for minor sicknesses; similarly it sustains more accidents at home as well as in the factory. Clearly a promising method of tackling reduction of accidents is to exclude from risk those possessing this tendency to sustain accidents. One question awaits further investigation, namely, whether any relation exists between the tendency to sustain major and minor accidents.—Medical Research Council 34, London, 1926; Abstr. *Bull. Hyg.*, December, 1926.

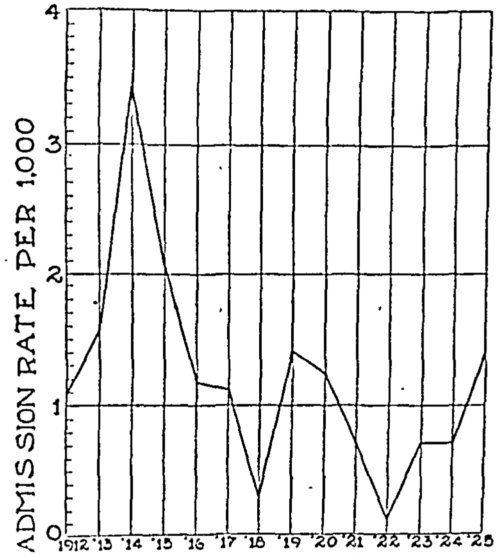
HEAT INJURIES

A PREPARATORY STUDY FOR EXPERIMENTAL HEAT-STROKE

E. G. WAKEFIELD, M.D.
AND
W. W. HALL, M.D.
Lieutenant, M. C., U. S. Navy
WASHINGTON, D. C.

In the latter part of the summer of 1926, several patients suffering from the injurious effects of heat were admitted to the medical service of the Naval Hospital, Washington, D. C., and all recovered uneventfully except one. This patient was left with some mental confusion and somatic delusions which he still had at the time of discharge from the hospital. A review of the subject at this time revealed that very little is known of the mechanism of production of the various forms of heat injury.

As a preparatory study to experimental investigation in heat-stroke in dogs, it was decided to make a study of heat injury in the United States Navy over a period of several years. In this report, besides giving the aspects of heat injury in the navy, we shall give as concisely as is possible an historical sketch which includes the theories, clinical observations and studies in the past. These will be referred to in a future communication.



Heat injuries in the United States Navy, including heat cramps, heat exhaustion, sunstroke and thermic fever, for the fiscal years 1912-1925.

The various heat injuries that occur in the fire and engine rooms of ships have been of particular interest to naval medical men since the advent of steamships in the navy. Many accurate descriptions have been given of these, at times, wholesale injuries. To attempt to add to these descriptions would be superfluous. Gihon[1] was the first medical man of our navy to mention the effect of heat on men in the fire room of naval vessels. Gihon writes: "Dr. Kitchen informed me that while surgeon of the monitor *Dictator* it was common for men to be brought to him for treatment with coma, stertorous breathing, great heat of the skin, full quick pulse and often convulsions. The cause was manifestly enough the exhausting labors of a watch in the fire room, where the temperature averaged 145 degrees." In another communication this writer[2] cites that instances of heat-stroke were undoubtedly produced in the "old navy," when the significantly termed "sweat-box" was a favorite means of punishment. "Men fell forward unconscious, with burning skin and bounding pulse, when the doors were opened after a brief period of confinement in the coffin-like boxes in which they were compelled to stand upright, and were placed on the sicklist as suffering from that indefinite affection 'adynamia.' "

In 1913, Fisk[3] supplemented Gihon's work and brought the available naval statistics up to July 1, 1911. The many factors of hygienic importance concerning the clinical aspects of heat injuries have been described from time to time. Of these reports, the following may be mentioned along with Gihon's and Fisk's works: Gatewood,[4] Grunwell,[5] Pryor,[6] and, more recently, Phelps.[7]

Table 1 and the chart present the heat injuries as they have occurred in the navy from July 1, 1911, to July 1, 1926. During this period, there were 2,049 instances of heat injury, sixteen deaths and eight invalided from the service. There was a total of 9,234 days sick. The percentage of mortality, based on morbidity, was 0.07; and the percentage invalided from the service, based on morbidity, was 0.03. The total number of days sick is a little high because all those admitted with a heat injury diagnosis which was changed while the patient was under observation were disregarded. The average number of days sick was 4.5. This study supplements Fisk's work, which incorporated Gihon's statistics. Fisk's table showed a total of 2,855 cases, thirty-five invalided from the service, twenty-two deaths and 12,849 days sick, with an average of 4.5 days sick. The remarkable thing shown in table 1 and the chart is the relatively small increase in the number of heat injuries with an actual decrease in rate per thousand in the navy during the Great War in view of the fact that there were so many more men in the service at that time.

Beginning with statistics of July 1, 1923, and ending Jan. 1, 1926, a study was undertaken to see whether there was any evidence which indicated that acclimation was a factor in the production of heat injury. The United States and its possessions were divided into two sections. The total number enlisting from the various states during this period was ascertained from Bureau of Navigation reports. From the "F" cards on file in the Bureau of Medicine and Surgery, the dates of birth, the approximate dates of enlistment, and the places of birth of the men suffering from heat injuries in this period were ascertained. This, in all probability, for practical purposes, formed a rough basis in determining whether a man was a native of the northern or southern section of the United States. The results of the study are presented in table 2.

This study would appear to indicate that those born and reared in the northern part of the United States are somewhat more susceptible to heat than those of the southern section. If this statistical analysis can be trusted, it supports the common belief that acclimation is a factor in the development of heat injuries.

TABLE 2.—*Acclimation as a Factor in the Production of Heat Injury*

	Number Enlisted

HISTORICAL

Heat-stroke or sunstroke is the oldest known disease.[8] The ancients associated the disease with Sirius, the dog star, and dog days. This association is probably accounted for when it is recalled that in the summer months Sirius follows the sun and is seen in the evening twilight. The oldest records of the disease are the biblical cases. In the fourth book of the Kings, Chapter IV, verses 18 to 20, inclusive, the following is found: "And the child grew. And on a certain day, when he went out to his father to the reapers, he said to his father: 'My head acheth, my head acheth . . .' And when he had taken him, and brought him to his mother, she set him on her knees until noon, and then he died." In the apocryphal book of Judith, chapter VIII, verses 2 and 3, is found: "And her husband was Manasses, who died in the time of the barley harvest; for he was standing over them that bound sheaves in the field; and the heat came upon his head, and he died in Bethulia, his own city, and was buried there with his fathers." One of the oldest records of the occurrence of the disease at sea is that of the British frigate *Liverpool*. In 1841, this vessel was proceeding from Muscat to Bushire; the weather gradually became warmer; double awnings were spread, the decks kept constantly wetted, and every precaution used to prevent exposure of the men; yet in one day, from a species of coup de soleil, three lieutenants and thirty men were lost. It was stated that at one time the decks resembled a slaughterhouse, so numerous were the bleeding patients.[9] In Peking, in July, 1743, 11,000 persons are said to have perished on the streets from the effects of heat.[10]

From biblical times until 1852, all instances of heat-stroke were confounded with apoplexy. This point is clearly illustrated by the writings of Forestus,[11] in 1562. Baglivi[12] of Rome, in 1694 and 1695, observed an epidemic of apoplexy which was imputed to the unusual condition of the weather in those years. About the first of October, 1695, there were fifteen days of rain which was followed by an outburst of apoplexies. Baglivi must have realized the many factors that entered into the disease. He mentions mental distress (referring to the wars in Europe at this time), the rain, the wind, the earthquakes and the inadequate supply of food. Lancisi, according to Levick,[13] was the first to publish evidence of the influence of hygrometry in the etiology of heat affections. Heat-stroke in animals other than man was recorded by Mosley[14] in 1803.

In 1789 Dr. Benjamin Rush[15] called attention to a disorder occasioned by the drinking of cold water in warm weather and described the symptoms of heat-stroke very accurately. The drinking of water, of course, was a symptom of the disease rather than the cause. The idea that the intake of cold water was the cause of the disease went so far that in the summer of 1814 the pumps in Philadelphia were posted with cautions, by the order of the Humane Society, against sudden death from drinking cold water.[16] J. Watts, Jr.,[17] protested against attributing to water the effects of heat. This observer was probably the first to note that the body temperature was elevated in major heat affections. W. W. Gerhard[18] clearly separated the instances of heat-stroke from apoplexy by noting that there were no gross changes in the brain in the former. Andral[19] of Paris was the first to note the relation between high atmospheric temperatures and heat-stroke. He gave the first accurate account of the major postmortem findings, namely, petechiae, liquid blood and venous engorgement. In 1834, J. J. Russell[20] of the British army noted pulmonary congestion, and he erroneously concluded that the chief seat of the mischief was in the chest.

Heat-stroke occurring in places other than in the sunlight was first fully described by Condie.[21] This observer was the first to emphasize the humidity of the air as an important etiologic factor. His patient, a negro preacher, was suddenly attacked, during his sermon in a crowded and overheated church, by convulsions alternating with tremors. The pupils were dilated, the pulse thready, and the skin covered with cold, clammy sweat. In brief, this is a good clinical history of heat-stroke.

The best illustration of the confusion which arose after the observation had been made that major heat injuries could be produced elsewhere than in a blazing sunshine is found in the many names the disease has received—heat-stroke, ictus caloris, prostratio thermica, coup de chaleur, colpo di calore, Hitzschlag, Warmschlag, heat-apoplexy, heat-asphyxia, heat-dyspnea, heat-exhaustion, thermal, thermic fever, ardent fever, phrenitis aestiva, phrenitis calenture, erethismus tropicus, insolation and siriasis.

From the time of Claude Bernard's[22] experimental work on the effects of heat, the theories of the disease are largely based on experimental observations, which will be given in a future communication.

The first therapeutic measures recorded consisted largely of "spiritual healing," but the possibility of a physical element is introduced. After the Staff of the Man of God had been placed on the face of the Shunammite's child and failed, we read: "And when Elisha was come into the house, behold, the child was dead, and laid upon his bed. . . . And he went up, and lay upon the child, and put his mouth upon his mouth, and his eyes upon his eyes, and his hands upon his hands; and he stretched himself upon the child, and the flesh of the child waxed warm." Artificial respiration or the carbon dioxide therapy? Blood-letting, the therapeutic sheet-anchor through all the ages, a procedure which Weir Mitchell insisted on having after he had largely recovered from sun-stroke (eleven days), has been a favorite treatment in the past and even now in "selected cases." Lancisi, as early as 1739, recommended the use of iron in the debilities following heat injuries. The origin of this beneficial therapy undoubtedly is due to the severe secondary anemia which followed the bloodletting

The use of cold applications was first mentioned by Coates, and became so popular, and perhaps overused, that in 1854 Swift[23] made the following statement: "Indiscriminate use of cold affusions is productive of harm. Injurious and often fatal effects result from them." Cautious application of ice over the whole body was first advocated by Darrach.[24] The first fully intelligent application of cold was probably made by Levick[25] in 1856. His patient had a temperature of 109 F., and recovered by using cold applications. Opiates have long been a favorite method of treatment of sunstroke. They were first recommended by Rush.[15] Ether and chloroform are favorites for convulsions. The immediate removal of the patient from the heat, loosening and removing tight clothes, and reducing body temperature by any means have sufficed in most cases. The importance of this treatment has been shown by the British army surgeons[26] In a condition in which either the injury is acutely fatal or the imminent danger soon passed, it is not hard to understand why so many remedial measures have been used, and results claimed from their employment.

COMPLICATIONS AND SEQUELAE

In individuals that survive an attack of heat-stroke, it is not uncommon for symptoms to appear which indicate that, though life has been spared, some enduring mischief has been done. Immediately following the return of consciousness there may be speech disturbances, difficulty in swallowing, disorientation, hallucinations, delusions, paralysis or psychosis. In the patients who recover completely there may be severe diarrhea, apathy, loss of appetite, headaches and hyperirritability of the muscles for several days following the attack. In those once affected by heat there is frequently a subsequent hypersusceptibility. During convalescence there is an increased susceptibility to all sorts of infections Reid's[27] studies show that pneumonia occurs in 10 07 per cent of cases. In general the sequelae may be divided into those referable to the muscles or to the peripheral nervous system In referring to the frequency of infections during recovery from heat injuries, H. C Wood[28] agreed with Weir Mitchell that chronic meningitis is the most common sequela.

Recently an ex-soldier came under observation for treatment of vague gastric complaints and constipation. He was a white man, aged 47, who, fifteen years ago, had an attack of heat-stroke while in the army on duty on the Mexican border. The attack came on suddenly with a loss of consciousness, which lasted several hours. After regaining consciousness, he slowly recovered. Neurologic examination, when we first saw him, revealed absent knee-jerks, dilated pupils which did not react to light, and swaying in the Romberg position. Repeated serologic examinations for syphilis, before and after provocative arsphenamine, and examinations of the spinal fluid failed to show evidence of syphilis. The cell counts and chemical examinations of the spinal fluid were negative The patient stated that, since he had sunstroke, he had been susceptible to heat, and had had frequent headaches and visual disturbances. He had also been unable to stand with the eyes closed.

Messiter[29] observed hemiplegia in a boy of 4 years, the day following sunstroke. According to this observer, Surgeon General Maclean (of England) stated that he never saw hemiplegia follow sunstroke. Goebel[30] observed the absence of sweat and a positive Romberg as sequelae. Many different intra-ocular lesions have been described. Hotz[31] noted optic neuritis, neuroretinitis and detachment of the retina Dercum[32] reports instances of cord and peripheral nerve lesions. Space will not permit of further enumeration of the sequelae of heat injuries.

SUMMARY

1. A study of the heat injuries as they have occurred in the United States Navy since 1861 shows that there have been thirty-eight deaths and forty-three invalided from the service.

2. This study appears to indicate that the incidence of heat injuries is greater in those born and reared in the northern section of the country than it is in those from the South

3 There have been observations on heat injuries from biblical times up to the experimental era. Claude Bernard's investigations on the raising of body temperatures of birds and mammals by the application of artificial heat marks the beginning of this era.

TREATMENT OF NEUROSYPHILIS BY MALARIA

REPORT ON THE THREE YEARS' OBSERVATION OF THE FIRST ONE HUNDRED PATIENTS TREATED *

PAUL A O'LEARY, M D.
ROCHESTER, MINN.

The first and second years' observations on the results of the treatment of neurosyphilis by means of malaria were given in two previous reports[1] I now report the status of the original 100 patients treated by this method, and also call attention to other features noted in the observation of 113 patients treated subsequently.

The treatment by malaria in the Mayo Clinic has been used particularly in the resistant parenchymatous forms of neurosyphilis, including the persistent and incapacitating gastric crises, "lightning" pains in the legs, and the optic atrophy of tabes dorsalis Enthusiasm has not as yet carried us to the point of applying the treatment to patients with the acute signs of syphilis or the latent form of the disease Neither have the proved standard methods of treating neurosyphilis by the use of arsphenamine, tryparsamide, intraspinal medication, mercury or bismuth, and sodium iodide intravenously been discarded because, according to Stokes and Shaffer,[2] the majority of our patients with the early manifestations of neurosyphilis respond favorably to one or other of the modifications of these established systems. To the remaining small number of patients who do not derive satisfactory clinical or serologic results from these specific measures and to those who are admitted to my service showing the early clinical and laboratory signs of general paralysis, treatment by malaria is recommended because it has accomplished more for such patients than any previous combination of drugs or systems of therapy which I have tried.

There has not been any conclusive evidence advanced since the first report of Wagner von Jauregg [3] to explain the mechanism by which the results of malaria treatment are accomplished Subsequently in this paper I shall compare the clinical results in the group in which the plasmodia were found in the blood stream without pyrexia with those in which the course was pyrexial.

I believe it is well to call attention again to the fact that the method is not without hazard; that the patient must remain for approximately a month in an institution organized to meet the emergencies that occasionally arise.

STATUS OF THE CASES OF GENERAL PARALYSIS PREVIOUSLY REPORTED

A review of the present status of the original 100 patients inoculated with *Plasmodium vivax*, of whom fifty-seven showed early signs of general paralysis, indicates that practically 50 per cent of the latter are now in complete remission and have been so for from eighteen months to three years, and that an additional 18 per cent are in partial remission or improved in one manner or another

My conception of what constitutes complete remission in general paralysis is not based on serologic reversals or on the disappearance of the objective signs of the disease, but is estimated on the patient's economic status as a result of the treatment If a laborer is paroled from an insane asylum and again becomes a wage-earner, or if a baggage master, after six months' enforced idleness, returns to his work and is promoted to tariff clerk, or if a physician who was forced to give up his practice now insures a satisfactory income by raising chickens, or if a lawyer following a malaria course has retained a successful office practice for the last twenty months, the results may be interpreted as remissions On the other hand, if a railroad engineer was not permitted to drive an engine but supported his family by working as an engine hostler, or if a bank cashier now satisfactorily acts in the capacity of a bookkeeper at one-half his former salary, the results are interpreted as improvement or partial remission. Many of the patients have been re-examined by the neurologists at approximately six-month intervals to determine whether there has been any regression in the neurologic objective data The results have been negligible on the whole and of no significance in defining the degree of improvement If the time arrives when the term cure rather than remission is used, the assessment of the disappearance of the neurologic signs will be warranted.

SEROLOGIC DATA

The longer the observation period, the greater the number of serologic reversals noted. Clinical improvement is not always paralleled by serologic improvement, although practically all the patients who have been benefited clinically have also shown a decrease in the intensity of the Wassermann or Kolmer reaction and a decrease in the number of lymphocytes in the spinal fluid Of the twenty-eight cases of general paralysis in which complete remission was established, the serologic reactions of the spinal fluid and blood were completely reversed to negative in nine. The reversal to normal of the reactions of the blood and spinal fluid was, however, unaccompanied by clinical betterment in a few instances In one case which was in remission for two years and in which the serologic tests had remained completely negative for eighteen months, death occurred unexpectedly during a paretic convulsion Although I do not believe that the serologic data alone warrant prognostic deductions, I have been impressed with the absence of any serologic relapse in the entire series. This is significant in view of the fact that cases of parenchymatous neurosyphilis are prone to manifest persistently positive serologic reactions, and especially a tendency toward frequent relapses in the state of the spinal fluid.

The second most significant observation in the study of the serologic evidence has been the prognostic value of the colloidal benzoin test. Particularly following treatment, I have been loath to attach much significance to one or two such reactions, believing it necessary to have at least three typical zone reports before attaching any prognostic significance to them This applies to the colloidal gold test as well as to benzoin In this group it is striking how frequently a paretic type of curve was reduced to a tabetic type and remained so if remission followed In several instances such change has preceded the clinical improvement. It is difficult to explain why this reversal is so much more pronounced in these cases than in cases of the same type of syphilis in which standard methods were followed in treatment. Marked reduction in the pleocytosis was frequently noted at the end of the fever course. On one occasion a drop from 189 to six small lymphocytes in the spinal fluid was recorded two days after the last paroxysm. Moreover, the disappearance of large lymphocytes and the occasional polymorphonuclear leukocyte from the spinal fluid was often noted at the end of the fever course.

CLINICAL RELAPSE

There have been two patients in this group who have relapsed clinically. Complete remission had lasted for twenty-four and eight months, respectively, following the malaria course, and both patients were prompted by their apparent well being to refuse further antisyphilitic treatment. Repeated attempts at reinoculation were unsuccessful following the relapse. In another case (already referred to) which was in partial remission, during eighteen months of which the tests of blood and spinal fluid had been repeatedly negative, death occurred suddenly during a paretic convulsion In a small group in which partial remission following the fever course permitted a return to the original occupation, there has been slow, almost insidious, mental deterioration. The home physicians of two of these patients compared their regression to that of senility. It is worthy of note, also, that some of the patients whom we classified in the unimproved group, who previous to the malaria course had been irritable, troublesome and of great concern to their families, have remained docile, absent-minded and ambitionless following the course of fever It is possible that this course of events is the result of the injury that syphilis has produced in the brain tissue and that treatment by malaria has held in abeyance, for the present, further degeneration

REINOCULATION AND IMMUNITY

In those cases in which a satisfactory fever course was not followed by clinical improvement, reinoculation failed to produce a second course with one exception. In this case five pyrexial attacks in a second course were followed by spontaneous abortion of the malaria. In our experience with inoculation of malaria, it is not unusual to find patients who are immune to the plasmodia at the time of inoculation, and others who acquire this immunity after a few or several pyrexial bouts. This has been noted particularly in patients who give a reliable history of previous malarial fever. There have been seven cases in which it was impossible to produce chills and fever by repeated inoculations, and it was not possible to recover the plasmodia in the blood stream following inoculation with various strains of the organism that were producing successful takes in other patients. These seven patients are undoubtedly immune to the disease.

The group in which spontaneous abortion of the malaria has followed from six to fourteen chills has been particularly studied for therapeutic effects. Of these twenty-two cases the plasmodia were retained in the blood in ten, although the course was afebrile; in the remainder the organism was not recovered. In this group of aborted malaria, the best therapeutic effect followed the greatest number of chills; after six or less pyrexial attacks practically no benefit was derived from the inoculation, while those in which more than six occurred showed varying degrees of benefit. The presence of plasmodia in the blood for many days after the chills stopped spontaneously did not increase the degree of benefit. This confirms my previously recorded impression that the therapeutic benefits from malaria treatment are more dependent on the fever than the presence of the plasmodia. The fact that other fever-producing substances have been less effective therapeutically than the malaria suggests that there is still some unexplained mechanism involved. The evidence of Weichbrodt and Jahnel,[4] and more recently Schamberg and Rule,[5] has demonstrated the influence of fever in cases of experimental syphilis.

In the cases in which chills and fever spontaneously disappeared while the plasmodia were still retained in the blood stream, the use of foreign protein substances has been successful in reestablishing the bouts of fever. The intramuscular injection of whole milk, typhoid vaccine or plasmodia-free whole blood, or the intravenous injection of 2 or 3 cc. of malarial blood will invariably provoke the chills and fever within twenty-four hours. When the plasmodia were not demonstrable, this method has been of no avail.

In six cases the chills were stopped because of severe toxemia, convulsions or toxic hepatitis early in the course of the fever. In two of these, in which there were nine and eight pyrexial bouts, respectively, there was slight improvement, while in the remainder neither benefit nor appreciable ill effect occurred.

It would appear from a study of this group, and indeed of the entire series of cases, that the point which I mentioned in my first report is still tenable; namely, that the greater percentage of remissions was noted in the cases in which bouts of fever were higher and more prolonged.

THE NONPARETIC GROUP

Of the thirteen cases in which the disease was classed as asymptomatic paresis, or paresis sine paresi, benefit has been shown in six by gain in weight, increase in strength and ambition, and general improvement. Of these the reaction of the blood and spinal fluid was completely reversed to negative in four, and in the remaining two the factors in the spinal fluid became negative, except the Kolmer reaction, which remained weakly positive. It is to be noted that the patients who showed the most satisfactory clinical and serologic results received intensive antisyphilitic treatment following the malaria.

In uncomplicated cases of tabes dorsalis the results have not been better than in those treated by the routine measures, and I do not feel justified in these cases in adding the additional risk of malaria treatment. However, in those serologically negative cases of tabes, with persistent lightning pains or gastric crises, in which continued use of arsphenamine, mercury and iodides has offered little relief, such treatment has brought about more improvement than has been accomplished heretofore. Of three cases in which intensive antisyphilitic treatment had been previously given for gastric crises without material improvement, the crises are practically relieved in two, after almost three years of observation. Similarly, of two cases in which the serologic data were negative and lightning pains were persistent, almost complete relief has been accomplished in one, while in the second but slight amelioration of the pains has been noted. In these two groups inoculation was carried out late in the first year of the fever treatment, but since then inoculations of malaria have been used in three additional cases manifesting persistent pains in the legs, and in eight of those manifesting gastric crises; although the percentage of improvement is not as high, because of the larger series, the results definitely warrant the continuation of the method in these groups.

Of the seven cases of simple optic atrophy, only slight decrease in vision has occurred in three, in comparison with that noted previous to the course of fever, while in four loss of vision was progressive. In practically all the cases of this group there has been a decrease in vision toward the latter part of the fever course, which has progressed further during the administration of quinine. In only one of this group was there a suspicion that the vision decreased as a direct result of the malaria.

Of the six cases of asymptomatic neurosyphilis, definite serologic reversal has been found in one, while in the remaining five no material change has been observed as yet. There were six borderline types with taboparalysis, in all of which clinical improvement was manifested, but without any serologic changes of note. Of the original 100 patients treated, there have been six whom we have not had the opportunity of examining during the last year.

In only five of the original cases in which malaria was induced was syphilitic aortitis evident because, early in the treatment, I purposely avoided inoculation in cases of cardiovascular disease complicating neurosyphilis. However, in all of the six cases in which necropsy was performed after the malaria course, definite syphilitic aortitis was found. During the past year there has been one case with aortitis and aortic regurgitation in which it was necessary to stop the malaria because of myocardial failure, but in the remaining twelve patients inoculated progression in the cardiac symptoms was not noted. Further observation is necessary to determine whether treatment by malaria has a beneficial effect on cardiovascular syphilis.

COMPLICATIONS

The complications that have developed during the course of fever have become less troublesome with continued experience. The blood urea is a valuable indication of the degree of toxemia of the inoculation malaria. I have likewise found tests of hepatic function of considerable help in estimating the severity of the postmalarial jaundice, a not uncommon complication in the more recent series. Three types of hepatic disease have been demonstrated thus far in the entire series. In three patients, syphilitic hepatitis, previously unrecognized, was aggravated by the treatment by malaria, but responded readily to mercury and iodides. Toxic hepatitis, probably of malarial origin, has been the most common type noted and has responded quite satisfactorily to the measures recommended by Wilhelm[6] for the treatment of postarsphenamine jaundice. Hepatic cirrhosis has been observed in one case. As previously mentioned, on one occasion evidence of myocardial failure developed toward the end of the course in a case in which there was aortitis and aortic regurgitation. Herpes simplex and labialis are quite common during the febrile course, and herpes ophthalmicus has resulted in serious sequelae lasting for nine months after the paroxysms. As would be expected in the treatment of general paralysis, all the mental complications from complete negativism to marked delirium may be encountered during the febrile stage. As the result of adhering to the seven-week course of quinine, there was only one recurrence of the malaria in the 213 patients treated.

MORTALITY

The mortality in cases treated by malaria, as reported by various observers, has offered a weighty weapon for the opponents of this form of treatment. Of the first 100 patients treated by this method nine are dead, a rate which compares favorably with that in any group of untreated cases of parenchymatous neurosyphilis observed for three years. Analysis of the causes of death shows that in two cases it was probably directly due to the malaria. In three others, the malaria undoubtedly acted as the predisposing factor, as the direct causes were bronchopneumonia, diphtheria and erysipelas. These infections were acquired shortly after the malaria was stopped or during the last few days of the fever course when the patients were debilitated and exhausted. In two cases death was caused by general paralytic convulsions many months after the fever course; in these I believe the malaria had no influence. In the eighth case death was due to suicide, and in the ninth to infectious meningitis a year after the malaria course. So there have been actually only five cases in which death was influenced by the malaria, a surprisingly low figure if the severity of the fever course and the debility of the patient are considered. In the second group of 113 patients treated there have been five deaths; in two of these the malaria was a predisposing cause, while accidents accounted for two more, and suicide for the fifth.

Necropsy was performed in six of the nine fatal cases. Acute splenitis and long-standing aortitis have been demonstrated in all the cases, but in none was death in any way attributable to the aortic lesion. Microscopic study of the brains has not been carried out in detail, but will afford material for a separate study. The reports of Gerstmann,[7] Sträussler and Koskinas[8] and, more recently, that of Freeman, indicate that the clinical results from treatment by malaria in general paralysis are attributable to organization in the meninges and around the blood vessels by means of deposits of fibrous tissue. Particularly significant has been the absence of *Spirochaeta pallida* in the brains studied. These reports are most encouraging, and Freeman[9] prophesies that we may eventually be warranted in talking of the cure of general paralysis following the treatment. Until more evidence has been accumulated to support this impression, I believe we must be satisfied in estimating the results in terms of arrest or remission because, even though there has been a demonstrable pathologic change in the meninges and about the blood vessels following the treatment, the fibrosis which takes place will result in a group of symptoms which may eventually be recognized as the residue of parenchymatous neurosyphilis. The use of such terms as "arrested" or "burned out" and "paroled general paralytic" will be justifiable in this group until sufficient time has elapsed and further pathologic studies have shown that the cure of neurosyphilis is possible. The value of the use of the malaria treatment early in the course of neurosyphilis is again emphasized by these pathologic studies.

* Observation has now extended from two to three years.

POSTMALARIA TREATMENT

The postmalaria antisyphilitic treatment is an adjunct. The most pronounced remissions and serologic reversals have been observed in those cases in which the most systematic and intensive treatment was carried out after the course of malaria. However, pronounced remissions and serologic reversals have been encountered in some cases in which only the fever course was undertaken. As might be expected, in the cases in which intraspinal measures were used in conjunction with arsphenamine intravenously, mercuric succinimide intramuscularly and sodium iodide intravenously, there were more serologic reversals than in those in which only tryparsamide and bismuth were administered. There is, however, little choice between these two systems of treatment, and the selection has been dependent on the patient's age and general condition, and the clinical result of the malaria four months after the fever course.

Four different strains of *Plasmodium vivax* have been available for use, and the third strain has passed through 525 different hosts that I have record of. This has been due to the successful transfer of the strain to seven different hospitals in the Northwest. Successful inoculation was carried out in these institutions seventy-two hours after the blood was withdrawn, by the use of a solution containing 5 per cent sodium citrate and 0.2 cc. of 50 per cent dextrose solution, into which 20 cc. of defibrinated (by agitation) malarial blood was injected. The blood was transported in vacuum bottles kept at body temperature.

There has not been any material change in the virulence of the organisms by passage through these numerous hosts. On two occasions, after the malaria in three or four cases in succession had aborted, it seemed as though the organism was losing its potency; but when it again developed its former virulence in subsequent inoculations, it was inferred that the organism was not at fault but rather that the resistance of the patient to the plasmodium was sufficiently high to prevent the chills and fever.

SUMMARY

In a series of 100 patients with various manifestations of neurosyphilis who were inoculated with *Plasmodium vivax* between June, 1924, and February, 1926, there were fifty-seven cases of general paralysis, of which twenty-eight (49 per cent) are still in remission as measured by the economic status of the patients. Of the thirteen patients presenting the syndrome of paresis sine paresi or asymptomatic general paralysis, six have been materially improved, and the factors in the blood and spinal fluid have been reversed to normal in four. The evidence still supports the assertion that in the serologically negative cases of tabes with persistent lightning pains or gastric crises, malaria inoculation is beneficial if the general condition of the patient will permit him to tolerate it. Likewise, in the group with optic atrophy benefit has accrued: in four of the nine cases in which this treatment was carried out, the loss of vision has been apparently arrested.

Table 2.—*Results of More Than One Year's Treatment in Fifty-Seven Cases of General Paralysis (Second Group Reported)*

Status of Patient	1925		1926	
	Cases	Per Cent	Cases	Per Cent
Remission	22	39	28	49
Improvement	9	16	10	18
No change	15	26	6	11
Death during year	7	..	1	..
Unknown	4	..	4	..
Clinical relapse	..	..	2	..

The method of treatment is not without risk, as evidenced by a mortality of 5 per cent, only those cases in which the malaria was a factor being considered. For parenchymatous neurosyphilis in debilitated and senile patients, tryparsamide is still to be preferred.

The clinical results have been more pronounced when the fever treatment was instituted early in the course of the general paralysis before much degeneration had taken place, but striking results have been noted in cases in which the clinical signs of general paralysis were present four years before the inoculation. The duration of the syphilis has not been a factor in the end-results.

The recent reports of the study of the brain in cases of general paralysis in which death followed a malaria course indicate that healing and deposition of fibrous tissue have actually taken place in the meninges and around the blood vessels. Such data suggest the possibility of some day speaking of the cure of general paralysis, but experience with this disease must be supplemented by many more years of observation of the pathologic as well as the clinical results before such insinuations are warranted.

The longer the periods of observation, the greater the number of cases in which the condition of the spinal fluid and blood is completely reversed to normal. It must be borne in mind, however, that the serologic changes are not always paralleled by clinical improvement. This is confirmed by the observation of cases in complete remission in which no serologic changes are manifested; on the other hand, a case with complete change in all the factors in the spinal fluid and the blood may be suddenly terminated by death from general paralysis. In my experience the changes in the colloidal benzoin and colloidal gold tests are of more prognostic significance following treatment by malaria than they have been in other forms of treating neurosyphilis. The change from a first to a second zone type of curve and eventually to a flat or negative curve has, on numerous occasions, preceded clinical improvement.

Experience with the fever treatment of Wagner von Jauregg during the last three years in 213 cases in my service, and in sixty-five additional cases in a neighboring hospital with which we cooperated, has definitely proved that it is the most valuable method of treatment suggested for paretic parenchymatous neurosyphilis, notwithstanding the fact that it is attended with definite risk. I have demonstrated to my own satisfaction that antisyphilitic treatment is an essential adjunct after the course of malaria.

ABSTRACT OF DISCUSSION

Dr. Harold N. Cole, Cleveland: We have now been using this malarial therapy for something like two years and have treated about 200 cases. Although we wish to be conservative, we are enthusiastic about the results of the treatment. There are practically no patients who have not shown some benefit, many of them being of the type that does not respond to other types of treatment. We are now using this therapeutic measure in cerebrospinal syphilis, in cases that have been resistant to other methods. The fact that a public accountant who has not been able to add up a column of figures and who, within six months after this treatment, is able to take up his former occupation would certainly make one think there is something in the treatment. Many of the patients now show negative laboratory results. This may not occur shortly after the course, perhaps not for a year, but it is surprising then to find that everything is negative in the way of blood and spinal fluid tests. I should like to subscribe to Dr. O'Leary's remarks regarding the addition of foreign protein to stir up the activity of the fever after it has sort of died out. This can be done with great success. We have used this treatment in the control of cases of tabes dorsalis with crises; and as a result I have recently seen two severe cases in which there has not been trouble with these crises for a year. We have not seen much result in the cases of optic atrophy and naturally would not expect to see any when the damage has already been done. We have not attempted to give any second courses of malarial therapy as yet. If this work is done by some one who has followed quite a lot of these cases I think it is not a dangerous procedure. If he has not had much experience there will be many disagreeable things. If the blood pressure comes down to 90 it is time to do something. In all these cases we use caffeine sodiobenzoate. If the patient does not respond well to this we stop the treatment. Usually this will bring the pressure up again and we shall be able to finish the treatment. Like Dr. O'Leary, our best results have been obtained in patients who have had from fourteen to eighteen chills. We have found that blood urea estimation is of value, but the blood pressure gives a better indication. The urea is rarely high without other signs; for instance, diarrhea and severe exhaustion and persistent vomiting. Incident to such experiences we have had good results with sodium bicarbonate. During the chill we take the temperature every twenty minutes to get the top. Otherwise this will be missed in many instances. There has been but one death in the last 100 cases and we think this is due to the fact that we have had more experience with the treatment. I think that in working with cerebrospinal syphilis and other types the prognosis is good, or not so bad as in some of the older risks.

Dr. Udo J. Wile, Ann Arbor, Mich.: We have used the same form of treatment in a much smaller number of cases. In the group studied, about forty cases, we have not yet seen any untoward symptoms. No patient has as yet died. In the group treated we must have another type of general paralysis than that seen elsewhere, or else the cases were of a much later type than those seen and treated in other clinics. We have seen remissions occur in exactly 10 per cent of the cases. In only three instances have we seen the patient improved to the extent that he has been able to resume his occupation. In those three cases, as well as in the others, we have not been able to see any change in the spinal fluid reaction. In analyzing this result I think it compares favorably with the remission under no treatment at all. With regard to finding spirochetes in the brain, the striking piece of work Dr. O'Leary mentioned is remarkable. In this connection, Foerster of Greifswald found in puncture of the brain live spirochetes in two cases treated with malaria, so the results are apparently not uniform. We did find one thing that was very convincing, regarding malaria and spirochetes. A young woman with multiple chancres was given the malarial therapy solely to find out whether there was any effect on the spirochete outside the spinal system. Within a short time all the spirochetes disappeared from those lesions, and the lesions involuted much more rapidly than they otherwise would have. I am greatly pleased with the results Dr. O'Leary and Dr. Cole have reported, for I have been on the point of giving up the treatment because I could not see that my results were in accord with others. I will now continue the work and see whether later results will not be more in accord with theirs.

Dr. Watson W. Eldridge, Jr., Washington, D. C.: St. Elizabeth's Hospital in this city, where my work is carried out, was the first place in this country to undertake the malarial treatment of general paralysis. I inoculated the first patient in December, 1922, and we have treated approximately 275 cases since. It is apparent, therefore, that some of our cases were treated more than five years ago. A recent survey of our work showed that remissions had occurred in 61 per cent of the cases that had been treated for two years or longer. The percentage of complete remissions is not so high, only about 40 or less. I think we have been very conservative in our survey and I believe that an institution such as St. Elizabeth's is apt to be more conservative than the average clinic, in considering general paralysis. The serum determinations in 85 per cent of the cases have shown marked improvement and in a surprisingly large number have returned to normal. The improvement in the serum does not commence until about a year after the treatment and from then on becomes progressively more rapid, so that the greater the elapsed time since treatment, the greater the improvement. Does Dr. O'Leary transmit the malaria from one general paralytic patient to another? If not, how does he transmit it and keep his malaria active? I should also like to know whether, in the group in which the malaria failed to take, reinoculations were successful. I have had several inoculation failures, principally among colored males. In these cases inoculations repeated many times failed to take.

Dr. J. E. Moore, Baltimore: We have been using this treatment for three years and our results closely parallel those reported by the other speakers. There are many points of interest that cannot be brought out in a discussion of a few minutes, but there are one or two I should like to stress. Regarding incomplete remission, we have come to feel that this is a result poorer than no remission at all, or death. We have had several instances in which the patient has made a complete physical recovery from a rapidly advancing general paralysis, but has remained stationary or become worse mentally. Two or three such patients have shown no signs of dying in two or three years, and from the standpoint of the patient and his family this result is much more tragic than death. The possibility of such an outcome should be explained to the patient's family before treatment is undertaken. In the second place, we feel that in an ambulatory clinic malaria treatment is more or less a last resort from the economic standpoint. We have other methods of treatment available which enable us to get a fair percentage of complete remissions, especially in early general paralysis. In a small group of early general paralytic patients treated with tryparsamide we have obtained 57 per cent of adequate remissions. We have not been able to duplicate this result with malaria, chiefly because we have utilized this form of treatment for patients with more advanced general paralysis. It is difficult to ask a working man to give up the time necessary for treatment with malaria, when we can get good results by other means. I would emphasize the point regarding the serologic reactions. In most patients the spinal fluid does not begin to improve for at least a year after the inoculation. This seems to raise the question as to whether high temperatures are entirely responsible for the beneficial effects of the treatment. As has been said, many patients become serologically negative after one, two or more years. Was reinocculation done to produce a second attack, and if so, at what interval after the first? Will Dr. O'Leary tell us his experience with malarial treatment in optic atrophy and patients with eighth nerve deafness?

Dr. Paul A. O'Leary, Rochester, Minn.: In reading the summary, I failed to call attention to the fact that as a rule our patients with uncomplicated tabes dorsalis have not done well on malarial therapy, and we have not felt it worth the additional risk to place them on fever treatment. The patients with gastric crises and severe lightning pains have had a very decided lessening in the frequency of the pains and crises in practically 40 per cent in both groups. We have treated fifteen cases of primary optic atrophy, three of which have been materially benefited, in that they have shown no progression in the optic atrophy since the malarial course. I have had no experience with patients who had eighth nerve deafness. I think Dr. Eldridge answered Dr. Wile's point, in that it must be emphasized again and again that the longer the observation periods are carried out the more striking the clinical results become. Wagner von Jauregg called attention to this in his original communications, and it has been confirmed in our experience. Our patients have not been hospitalized general paralytics. We have, at Rochester, a state hospital for the insane, which is also using this method, and with its cooperation we have been able to maintain *Plasmodium vivax*. The second strain of the organism used in my service has now passed through 525 hosts that I know of. This has been accomplished by transferring it to various syphilologists in the Northwest. We have transported the malarial blood to Portland, Ore., and to Los Angeles, and successfully produced malaria. Inoculations have been made eighty hours after withdrawal of the blood from the host. We have reinoculated as many as six times those patients who have not developed chills and fever and have not been successful in obtaining a "take." We have also reinoculated patients who did not show improvement following the first fever course and have not been able to produce a second course of chills and fever. We have reinoculated as long as fourteen months after the first fever course but were not able to produce malaria. I have also noted that a patient with the agitated type of general paralysis may become a dull, morose individual following a malaria course and is certainly less care to his family than before the fever course. This kind of result is interpreted as a slight improvement, and I believe that the results of this type are not a contraindication to the method.

The Mind as Well as the Body Must Be Engaged.—Even bodily development is most successfuly achieved when the deeper forces are at work. The doctors have long recognized that healthful exercise is not simply a matter of muscular contraction. There must be an object, there must be interest, there must be exhilaration: to produce the best results the mind as well as the body must be engaged.—Lee: Play in Education, pp. 45-46.

FRACTURE OF THE XIPHOID PROCESS CAUSING CLONIC SPASM OF THE DIAPHRAGM *

CLARENCE E. BIRD, M.D.
Resident Surgeon, Peter Bent Brigham Hospital
BOSTON

To observe clonic diaphragmatic spasm is in itself sufficiently surprising, but to find as its probable underlying cause a fracture of the xiphoid process is still more so. Comparatively few instances of spasm of the diaphragm are found recorded, and, so far as can be determined, fracture of the xiphoid process is unique.

REPORT OF CASE

H. S., a married Russian-Jewish tailor, aged 48, was admitted, Oct. 10, 1921, with complaints which led to the diagnosis of duodenal ulcer. Roentgen-ray studies confirmed the impression and, October 13, under ether anesthesia, a transsection of the pyloric antrum with posterior gastro-enterostomy (Billroth II) was performed. The ulcer was situated on the anterior and superior surfaces of the duodenum, involving the cap along the lesser curvature. Because of the extensive surrounding induration and cicatrization, it was not removed. An appendix, noted by the pathologist to show "obliterative appendicitis," was excised, and the abdominal wound was closed in layers with chromic catgut, a small rubber tissue drain being left in the region of the duodenal stump.

The recovery from ether was stormy, with vomiting and raising of mucus, which accumulated in the pharynx. Between the third and sixth days after operation there were signs of infarction or pneumonia at the right base, and these observations were confirmed by a roentgenogram of the chest. Recovery from this complication was prompt and the patient was discharged on the nineteenth day after operation, without complaints. The wound was noted to be solidly healed.

Two years later the patient came to the outdoor department in answer to a follow-up letter. In spite of failure to adhere to a gastric five-meal regimen, he had been well until the previous two months, during which time he had had mild epigastric pain one-half hour after meals. No note was made as to whether this pain was similar to his previous ulcer distress.

On examination a moderately large hernia of the wound was found, and in the upper portion of it was felt an indurated mass thought to be a deep stitch surrounded by fibrous tissue. The patient was advised to enter the hospital for repair of the hernia.

This he failed to do, and was next seen in July, 1926, three years later. Because of new symptoms which had arisen, he was now quite willing to undergo a second operation. For two years, at intervals of from two weeks to a month, he had had attacks of sharp pain, starting in the midline between the xiphoid process and the umbilicus, and "shooting" to right and left along the costal margins toward the flanks. Each attack lasted over a period of from fifteen to thirty minutes. During this time he would lie down and compress his abdomen with his hands, partially relieving the distress. So far as he could tell, the attacks had no relation to his meals or to any other event, coming on at any time of the day but never waking him up at night.

Two weeks before admission the pain became more persistent, and for the first time was accompanied by a "shaking" of the abdomen. This "shaking" he involuntarily demonstrated to us from time to time.

Without obvious cause and without preparatory inspiration or other warning, and even while in the midst of a sentence, he would be suddenly interrupted by a series of from five to eight quick, moderately violent generalized protrusions of the abdomen. These spasms occurred within the time of one or two seconds, at a much faster rate than the heart's beat. I cannot be sure as to the relation to respiration, but I am under the impression that there was a cessation during this interval. At any rate there was no glottic spasm and no sound whatever.

There were several large and small defects in the linea alba between the umbilicus and xiphoid process through which the abdominal contents protruded on straining or coughing. In the upper portion of the wide scar could be felt a nodule which was the shape of the xiphoid, and which moved inward and upward as if hinged on the sternum. Once considered, this could be nothing other than a fractured ensiform cartilage, connected to the sternum only by fibrous tissue.

The patient had himself noted, and we were able repeatedly to observe, that manipulation of the wound in general would often bring on the clonic spasm. But still more striking was the almost unfailing production of the contraction by pushing the xiphoid inward and upward, by "pushing the button," so to speak.

Fluoroscopic studies of the diaphragm were, much to my chagrin, not made, and the patient, being in excellent general health, was operated on the morning after admission. At this time, the fractured xiphoid process was removed and the hernia repaired. In removing the xiphoid I attempted to demonstrate a direct anatomic connection with the diaphragm. Muscle fibers were not observed to be attached to the posterior surface of the process, but the diaphragm, seen and felt from within the peritoneal cavity, curved down, as usual, to the level of the upper portion of the ensiform cartilage to insert along the costal margin.

Coughing, retching and vomiting occurred as after the first operation, but there was no pulmonary complication, and he was discharged on the twentieth day after operation with a firmly healed wound in which there was no suggestion of a fascial defect. He had had no recurrence of spasm and no noteworthy pain. Gastro-intestinal roentgen-ray studies before discharge showed a gastro-enterostomy, functioning well. There was no evidence of a gastric or gastrojejunal ulcer. The duodenum was not visualized.

Since his discharge five months ago, I have seen this patient repeatedly. He occasionally takes a little sodium bicarbonate after eating to help raise gas from his stomach, but he has no more than slight discomfort and does not have the spasm of the diaphragm.

COMMENT

The fracturing of the xiphoid process in this case I am inclined to ascribe to the zeal of a junior assistant, who was probably holding a retractor at the original operation. The probability of this mode of fracture is at least strong, and serves as a warning against undue retraction against the ensiform cartilage. This fracture is, of course, most likely to occur when the fundus of the stomach or the region of the dome of the diaphragm is exposed through an upper midline incision.

Most of the reports of diaphragmatic spasm are found in Italian medical journals, though accounts in the English, French and German languages are to be singled out. The veterinarians have long been familiar with the disorder (first account in 1770).[1] They have described one case in an ox,[2] one case in a greyhound [3] and many instances in horses.[4]

The spasm may apparently be caused by irritation of the respiratory or phrenic center, by stimulation of either phrenic nerve anywhere along its course, or by direct stimulation of the muscle of the diaphragm.

A definite etiology has not been found for most of the cases reported, many being classified as "hysterical."[5] The probability that psychic stimulation may occur is strengthened by consideration of an itinerant who for years went the rounds of the German clinics exhibiting his ability to distort the lower thorax and abdomen [6] This he did by controlled action of the thoracic, diaphragmatic and abdominal muscles.

Cases have definitely followed encephalitis and influenza,[7] occurring with and without glottic spasm. In encephalitis and influenza, as well as in tics due to hyperexcitability (tetany, toxic nephritis [8]), the stimulus to diaphragmatic spasm may be central, in the phrenic nerve itself, or peripheral. In the so-called epidemic transitory diaphragmatic spasm,[9] a direct infection of the diaphragmatic muscle is probable.

A most striking example of phrenic nerve irritation was seen in a girl, aged 16, in whom a diaphragmatic spasm, without closure of the glottis, was initiated with each inspiration, the expanding left lung compressing the phrenic nerve against a cervical rib [10] The rib was removed, with complete cessation of the spasm. In our own hospital records is an account of a man, aged 63, who had recurring attacks of hiccups (diaphragmatic, thoracic [?] and glottic spasm)[11] over a period of years, following a severe brachial plexus injury of the left side, with extensive deep fibrosis of the cervical tissues.

In several instances one or the other phrenic nerve has been involved in an abscess, tuberculoma [12] or tumor of the mediastinum, while in others the spasm has been unilateral and synchronous with the heart beat,[13] suggesting direct irritation of the left phrenic nerve or the pericardial portion of the left diaphragm. In these cases the transmission of an action current from the cardiac muscle to the left phrenic nerve has been suggested.[14]

But direct irritation of the diaphragm is comparatively infrequent as a cause of diaphragmatic spasm. Examples of irritation by a gastric ulcer [15] (irritating the peritoneum over, or perforating into, the diaphragm), of rupture of the stomach (in horses), and of hemorrhage into the muscle of the diaphragm [16] (noted in a postmortem examination of a horse who had had diaphragmatic spasm) are on record Spasm caused by the irritation of a fractured xiphoid process is, in all likelihood, similarly due to muscle, or nerve ending, stimulation.

LENS PROTEIN AND ITS FRACTIONS

PREPARATION, AND IMMUNOLOGIC AND CHEMICAL PROPERTIES *

ALAN C. WOODS, M.D.
AND
EARL L BURKY, M S.
BALTIMORE

Our purpose is to report our experiments in the preparation of serologically pure fractional antigens of the crystalline lens, and our observations on the chemical and immunologic properties of these fractions.

This study was undertaken as the necessary forerunner of a proposed study of the possible rôle lens protein may play in lenticular disease. Before reporting our observations, the problem would be made somewhat clearer by a brief historical review.

In 1894, Morner [1] isolated from beef lens two crystalline fractions, which he called "lens alpha" and "lens beta," and an insoluble substance which he termed "albuminoid." In 1910 and again in 1922, Jess [2] reported his studies on the quantitative relationship of the alpha and beta crystallin at different ages, and in the normal and pathologic lens, noting the fact that in old age and in cataractous lenses the amount of the alpha fraction was decreased. In 1903, Uhlenhuth [3] reported his classic discovery concerning the immunologic properties of lens protein as a whole. Uhlenhuth's observation was that the protein of the lens differed immunologically from other protein bodies; that it was organ specific, and that it greatly lacked species specificity. The question arose as to whether the alpha and beta crystallins differed in their immunologic reactions, and this question has been studied, especially by Hektoen and Schulhof,[4] in the John McCormick Institute for Infectious Diseases.

Hektoen showed that the alpha and beta crystallins of the bovine lens were precipitogenically distinct. Also in practically all cases he found that in each of his preparations of alpha and beta the antigens were not serologically pure, owing to a small amount of the fellow crystallin. In only one instance did he procure serologically pure antialpha and antibeta serums.

As early as 1904 the observations of Uhlenhuth concerning the possibility of a relationship between lens protein and lenticular disease excited interest among clinicians and investigators In 1902, A. E Davis began working on this problem, publishing his first paper [5] on this subject in 1922. As a result of Davis' clinical observations, he is convinced that immunization with a preparation of the bovine lens has a definite effect on retarding the development of lenticular opacities. The same subject was investigated experimentally by Paul Romer. Romer's investigations extended from 1905 to 1914, and, while inconclusive, excited much controversy. In brief, Römer proceeded on the theory that the senile cataract was the result of some cytotoxin acting on the lens. His investigations [6] covered a wide field: (1) the effect of lens protein on the blood of various animals; (2) the action of lipoid and various poisons on the lens; (3) the permeability of the lens capsule to toxins; (4) a serologic study of patients with cataract, and (5) the effect produced by specific organotherapy with lens protein.

Experiments by Lazarew [7] and other investigators failed to show a relationship between lens protein and the formation of cataract, but there are certain points in Römer's work that cannot be ignored. Römer and Gebb were able to demonstrate, in the blood serum of a young diabetic patient with cataracts, antibodies specific for lens protein. They further showed that the lens capsules were permeable to cytotoxic substances, and that the cells of the lens were capable of uniting with substances for which they had specific receptors. Although Römer could not substantiate his hypothesis by experimental research, he was apparently convinced that the formation of cataract was due to a reaction taking place between the blood serum of the patient and the protein of the lens. General as is this statement, it is not to be lightly dismissed, for the brilliant experiments of Guyer and Smith [8] have recently reopened this entire question. Guyer and Smith, although not primarily interested in the immunologic reactions of lens protein, took advantage of the fact that in embryonic life the lens is surrounded by the tunica vasculosa and is therefore more subject to influences from blood serum than would occur later in life. These observers immunized fowls to rabbit lens protein, producing anti-rabbit lens serum. This serum was then injected back into pregnant rabbits at intervals of two or three days over a period of two weeks. There was a high mortality among these rabbits and the embryos; but among the sixty-one young surviving, nine showed ocular defects centered chiefly around the crystalline lens; imperfect development, or liquefaction of the lens; partial or complete cataract; or other ocular lesions which, in the opinion of these authors, were due primarily to the imperfect development of the lens.

STATEMENT OF THE PROBLEM

In view of the earlier observations of Uhlenhuth and Römer, the later observations of Davis, and the more recent startling experiments of Guyer and Smith, it seemed opportune to rework this entire field from the immunologic standpoint, in the hope that some observations might eventuate which would offer some rational clinical application. The enormous complexity of the problem has been briefly outlined by one of us.

Before any experimental or clinical studies were possible, it was necessary to obtain a reliable, stable preparation of the whole lens, and immunologically pure preparations of the lens fractions; and to determine if possible, the relationship, or serologic entity, of these fractions. This, accordingly, has been made the first problem in the proposed study.

EXPERIMENTAL WORK

In our first experiments we prepared the fractions of the crystalline lens in the manner used by Hektoen and Schulhof, and outlined by their predecessors. These preparations were made as follows: Bovine eyes were obtained from the slaughter house. They were opened by a section of the cornea, an incision was made in the capsule of the lens, and the lens was expelled. A number of these lenses, usually from twenty-four to thirty-six, in their wet, fresh state, were ground with sand until finally a smooth paste was obtained. Distilled water was added up to ten times the weight of the lenses. This was put in the shaking machine for two hours, and then allowed to stand over night; the next day, the mixture was given a slight swirl, and allowed to settle, and the supernatant turbid fluid was decanted. This was repeated until the mixture was free from sand. Sufficient sodium chloride was then added to make an isotonic solution (0.85 per cent), tricresol was added, and the mixture was allowed to stand at 37 C. for twenty-four hours. Aerobic and anaerobic cultures were then taken and if they were sterile, the mixture could be used in such concentration as was desired.

Such a preparation is turbid unless further filtered and is practically useless for precipitin tests. In order that the lens protein might be easily accessible at all times in more accurately quantitative form, a dehydrated mixture of the lens was prepared. This was done as follows: Pig or beef lenses, obtained as before, were crushed in their fresh state by being pressed between glass plates. The plates were pulled apart and the crushed lens material placed in a vacuum desiccator over calcium chloride with a measured vacuum equal to 700 millimeters of mercury. Rabbits' lenses, somewhat smaller, could be placed directly into the desiccator without danger of putrefaction; but with the larger lenses it was first necessary to crush them. When the dehydration was complete, the dried lenses were ground in a mortar; the resulting fine powder was returned to the desiccator for several days, and then stored in glass stoppered bottles. Such preparations as these, when a weighed sample is kept at from 90 to 100 C. for twenty-four hours, contain from 7 to 15 per cent moisture. Preparations of the whole lens could be made from this dry lens whenever desired. The strength of the various antigens was determined by dehydration to find out the total solid content (including salts), and by quantitative nitrogen determination to ascertain the protein content.

PREPARATION OF FRACTIONAL ANTIGENS

Alpha Antigens.—An aqueous extract of the whole lens is centrifugalized at a high speed for fifteen minutes, and the supernatant fluid decanted. The sediment represents the "albuminoid" fraction of Hektoen and Schulhof. Tenth-normal acetic acid is added to the supernatant filtered fluid until the maximum precipitate is obtained. The precipitate thus thrown down by the acetic acid is the alpha crystallin, while the supernatant fluid is chiefly the beta crystallin. The alpha precipitate is then dissolved by adding tenth-normal ammonium hydroxide and is again precipitated by the further addition of tenth-normal acetic acid. This procedure is repeated several times.

Beta Antigens.—The supernatant fluid, after the primary precipitation with tenth-normal acetic acid, is chiefly beta crystallins. This fluid is dialyzed in collodion sacks until the p_H of the surrounding tap water is reached. Tenth-normal acetic acid is again added to the solution, the remaining alpha precipitated, and the supernatant beta fraction again dialyzed. This procedure is repeated several times. These antigens were then properly injected into rabbits, and immune serums were thus obtained to a number of different preparations of this whole antigen and fractional antigens. These serums were examined against the various antigens in the precipitin test.

TECHNIC OF THE PRECIPITIN TEST

The antigens are diluted in physiologic sodium chloride solution to the different desired dilutions, usually from 1:100 to 1:100,000. The serums are usually undiluted. Occasionally, for exact determinations, they are diluted 1:2, 1:4, 1:8, 1:16 and 1:32. Tubes 8 mm. in diameter are used, and 0.15 cc. of antigen is added to the tube. The serum, of greater specific gravity, is allowed to run down the side of the tube slowly until it layers itself cleanly beneath the antigen. Fifteen-hundredths cubic centimenter of the serum is used. The tubes are kept at room temperature for one hour, when they are read as either positive, doubtful or negative, by the ring test. They are then shaken, kept one hour at room temperature, and read on a four plus scale, visible precipitins being used as the standard. They are kept overnight in the icebox, and again in the morning read on the same scale. Only a negative reaction was recorded, when the last icebox reading was clear.

All serums were kept in the icebox, either in a sterile condition or preserved by chloroform. All antigens were sterilized by passage through Berkefeld filters; their sterility was proved by culture, and they were then kept under sterile conditions in the icebox without preservatives.

All animals were bled before immunization was commenced, the serums that proved negative to lens antigens were used thereafter as negative controls.

RESULTS OBTAINED WITH HEKTOEN-SCHULHOF PREPARATION

Our results obtained with the antiserums produced by the injection into rabbits of the antigens perpared by the method outlined by Hektoen and Schulhof confirm almost exactly the results reported by these authors in their second report. While there was every reason to believe that the alpha and beta antigens are precipitogenically distinct, nevertheless a certain amount of cross precipitation was obtained.

Table 1.—*Whole Lens Antiserum with Whole Lens and Fractional Antigens*

Antiserum	Antigens	Results
Whole Beef Lens (34.1)	Whole Beef Lens	Positive 1:100,000
Whole Beef (34.1)	Alpha A. 1	Positive 1:100,000
Whole Beef (34.1)	Beta B. 2	Positive 1:12,000

Rabbits immunized to whole lens reacted with antigens of whole lens in dilutions of more than 1:100,000. The same whole lens antiserum reacted with alpha antigens in the same concentration. It reacted with the beta antigens in a concentration of 1:12,000. The results are shown in table 1.

Alpha antiserum reacted with specific alpha antigen in dilutions up to 1:100,000 (on the basis of total solids). These alpha antiserums, however, reacted definitely with beta antigens; in much the same manner they reacted with alpha antigens. Table 2 shows the reaction obtained with these typical antialpha serums.

Beta immune serums obtained by beta antigens prepared by this method show a precipitin reaction with beta antigen as high as 1:16,000 (on the basis of total solids) and do not show any reaction to any alpha antigens even after twenty-four hours' incubation. Table 3 shows the reaction of the typical beta antiserum.

Table 2.—*Reactions of Alpha Antiserum*

Serum Alpha (6364.2)	Antigens														
	Alpha Crystallin (A 16.11)							Beta Crystallin (B 12.0)							
	2,000	4,000	8,000	16,000	30,000	60,000	100,000	2,000	4,000	8,000	16,000	30,000	60,000	100,000	NaCl
Undiluted	4	4	2	2	2	1	1	2	2	2	1	1	1	1	—
1:2	4	4	3	2	2	1	1	2	2	2	1	1	1	1	—

Normal* serum	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

* Serum of rabbit used to produce antiserum, taken before immunization.

From the results of these titrations it appears that all antigens are immunologically active, and that the beta antigen, probably, is serologically pure.

A large number of alpha antigens were prepared according to the method outlined by Hektoen and Schulhof, and repeatedly purified by precipitation. Yet it was impossible to produce by this method any alpha serum which did not react definitely with beta antigens. An alpha antiserum with the greatest relative purity was then taken and absorbed with an excess of beta antigens over a period of twenty-hours. There resulted the complete removal of all antibodies to beta antigens, while the precipitin reaction of this absorbed serum to the alpha antigens was unimpaired. This indicated that the impurities lay in the alpha antigens, for had the alpha antiserum-beta antigen reaction been due to any alpha impurity in the beta antigen, the absorption of alpha serum with the beta antigens would have resulted in the impairment of the alpha antigen-alpha antiserum reaction, which was not the case.

Table 3.—*Reactions of Beta Antiserum*

Serum Beta (65.3)	Antigens										
	Alpha Crystallin (A 16.11)					Beta Crystallin (B 12.0)					
	2,000	4,000	8,000	16,000	32,000	2,000	4,000	8,000	16,000	32,000	NaCl
Undiluted	—	—	—	—	—	4	4	2	2	1	—
1:2	—	—	—	—	—	4	4	2	2	2	—

Normal* serum	—	—	—	—	—	—	—	—	—	—	—

* Serum of rabbit used to produce antiserum, taken before immunization.

It was quite evident, therefore, that in order to prepare reliable, serologically pure alpha and beta antigens, further investigation was necessary. The Hektoen-Schulhof method yielded antigens which definitely indicated that precipitin distinction existed between these two antigens; yet an alpha antigen could not be prepared by this method in a serologically pure condition.

IDENTITY OF THE ALBUMINOID FRACTION

In the first part of the investigation, an emulsion was made of the "albuminoid" fraction and injected into rabbits. The antiserum thus obtained was immunologically indistinguishable from a routinely prepared alpha antiserum reacting strongly with alpha antigen, and less strongly with beta antigen.

Later in the investigations, the "albuminoid" residuum, after the removal of the alpha and beta fraction, was purified as follows and an antiserum obtained: Desiccated lens was used. A 3 per cent suspension in tenth-normal ammonium hydroxide and 0.5 per cent tricresol was shaken over night in the shaking machine with glass beads. The next morning it was placed in the refrigerator, where it remained for a day. The sediment was then collected by centrifugalization and washed with water for a period of seven days, until the supernatant fluid no longer contained protein by the ninhydrin test. The sediment, 30 cc. by volume, was suspended in 120 cc. of tenth-normal ammonium hydroxide, shaken five hours, and then placed in the refrigerator over night. It was centrifugalized fifteen minutes at high speed. The supernatant fluid was dialyzed in collodion over night. The dialyzate was again centrifugalized and the sediment discarded. Sodium chloride was added to make a concentration of 0.85 per cent and tricresol to 0.5 per cent. This was injected intravenously into rabbit A7B1 in four doses, the first one 5 cc. and the other three 10 cc., twice a week for two weeks. Three days after the last injection the rabbit was bled and serum A7B1 obtained. This antiserum A7B1 reacted with alpha antigens up to 1 : 50,000 and did not give any reaction with beta antigens. In fact, it was by this devious route that we prepared our first serologically pure alpha antiserum.

For these reasons it appears to us that the "albuminoid" fraction is not a distinct serologic entity, but is definitely alpha crystallin, which is either enmeshed in the lens fibers and is so prevented from going into solution, or is an insoluble form of alpha antigen. We have not been able by any of numerous means to prepare a true solution of the "albuminoid" fraction.

In the light of these experiments, it appears impossible to expect serologically pure preparation of the lens fractions if the methods used by Hektoen and Schulhof are exactly followed. Further, the whole lens mixture prepared by the Hektoen-Schulhof method is difficult to use in the precipitin reaction, owing to the difficulty of passing it through a Berkefeld filter to obtain a water clear solution. Accordingly, we have tried a number of other methods of preparing whole lens protein and its fractions. For a long time our efforts were fruitless as regards the fractional antigens, the interaction between the alpha immune serum and the beta antigen persisting. We have finally succeeded, however, in obtaining preparations of alpha and beta antigens which appear to be serologically pure and which we have been able to reproduce with definite regularity. Our final methods of preparing whole lens protein and the alpha and beta fractions are as follows:

PREPARATION OF WHOLE LENS PROTEIN

A method of the preparation of the lens protein has been devised by Cecil, and has been adopted by the H. K. Mulford Company, which markets a 2 per cent solution of lens protein. This method of extraction is as follows: Fresh lens is treated with sodium chloride solution containing 0.5 per cent of sodium bicarbonate, in the proportion of 20 cc. to one lens. The lenses are crushed and as thorough an emulsion as possible is obtained; then 0.5 per cent phenol (carbolic acid) is added. This emulsion is kept in a refrigerator for forty-eight hours, and is then strained through gauze, and put through a Sharpless centrifuge twice. It is filtered twice through three thicknesses of coarse filter paper; then once through a Mandler filter with 5 pounds pressure and again with 11 pounds pressure. Finally it is passed twice through a Berkefeld filter, with 15 pounds pressure. There results a stable colloidal solution which has a distinct blue tinge.

In our earlier investigations, it was noticed that a weak solution of ammonium hydroxide was a better solvent for lens protein than was water. Accordingly, we devised the following method of preparing whole lens protein: Fresh lenses were treated with hundredth-normal ammonium hydroxide, shaken with glass beads in the shaking machine for about ten hours, and then placed in the refrigerator for forty-eight hours or more. Tricresol, 0.5 per cent, is added before the mixture is placed in the refrigerator. The material is then centrifugalized at high speed for one hour; the precipitate is discarded, and the supernatant fluid is filtered through coarse filter paper, three thicknesses, and then through Berkefeld filters for sterility. Aerobic and anaerobic cultures are made. If the cultures are negative, the resulting solution can then be used. The end-product is a clear lemon yellow fluid, the protein content of which is usually 1.5 per cent or less.

Table 4.—*Relative Protein Content, Percentage, and the Total Solid Content, in Various Antigens* *

Antigen	Preparation	Total Nitrogen	Nonprotein Nitrogen	Protein Nitrogen	Protein Percentage	Dehydration Total Solids, per Cent

* Analyses made by Dr. W. F. Perlzwig, through the courtesy of Dr. Longcope, in the chemical laboratory of the medical clinic of the Johns Hopkins Hospital.

More recently we have used the following method of preparing whole lens protein:

The whole lens protein is treated with hundredth-normal ammonium hydroxide and an emulsion is made, which is put in a shaking machine over night. "Alumina cream" [9] is then added to 10 per cent of the total bulk. The mixture is allowed to stand over night. The supernatant fluid is then decanted. The sediment is removed by centrifugalization. The supernatant fluid is passed through a filter once, then through a Berkefeld B filter at 8 pounds pressure. There results a solution which appears to be comparable to the solution prepared by further filtration. This has the advantage of being extremely easy to prepare. We have prepared numerous specimens of these antigens by these different methods. Tests fail to show the presence of any aluminum salts. ✓

To determine the relative values of these methods of preparation, we have extracted both the dry and the fresh lens with these methods, keeping all other steps in the procedure identically the same throughout. The total nitrogen and nonprotein nitrogen of these antigens were then determined, and the protein percentage calculated. The total solids, which includes not only the protein but all salts, was also determined by dehydration. Table 4 shows the results of these analyses.

---

[9] Alumina cream is freshly precipitated aluminum hydroxide made by precipitating aluminum chloride by sodium hydroxide and washed until free of excess alkali.

In obtaining the data recorded in table 4, the fresh lens preparation was made from twenty beef lenses with 400 cc. of solvent. The dried lens preparation was made for 12 Gm. of dried lens, which is roughly equivalent to twenty fresh lenses and 400 cc. of solvent. The percentage figures are reached by using the nitrogen factor for alpha and beta crystallin given by Hammersten, which is 5.94. The total solids are measured by dehydration. This dehydration process, of course, measures definitely all organic and inorganic salts as well as other constituents which are not included in protein percentage.

During the filtration of these lens antigens, it was noticed that the solution filtered more and more slowly, and that the end-product became more and more water clear as filtration proceeded. Accordingly, the different antigens were passed through new filters and the amount of the solution filtered before clogging took place was measured. It was found that 100 cc. of the antigen prepared by the Cecil method (with sodium chloride) passed through the filter before clogging occurred, but that all other solutions clogged the filter after 15 or 25 cc. had passed through. It also appeared that the absence of sodium chloride from the solution played an important rôle in the clogging of the filters, which seems quite natural when one remembers that sodium chloride inhibits to a certain degree the normal swelling of protein in the presence of alkali.

After the determination of the physical properties of these various preparations of antigens, we examined next their immunologic properties. Rabbits were accordingly immunized to a Cecil preparation of the antigens, supplied by the H. K. Mulford Company, and to an ammonium hydroxide extraction of the lens prepared by us; the exact protein percentages of both of these solutions were first determined, and the doses so arranged that the same amount of protein was received by the two series of rabbits. The only difference noticed between the antigens during the administration was that the ammonium hydroxide antigen had a somewhat corrosive action on the ear veins, while the Mulford preparation was much more readily tolerated by the rabbits. The rabbits were bled after the fifth injection, and both showed precipitins. At the end of the sixth injection, both showed strongly positive serums with homologous antigens. They were then bled from the heart, and the serums carefully examined in the precipitin test against the various antigens. A difference in the precipitin titers of the different serums was not noted. The serums were tested against the fractional antigens, and the results were most surprising. The reactions between the antiserum from ammonium hydroxide preparation and the alpha antigens was very much stronger than was the reaction between the antiserum produced by the Mulford preparation and the same antigens. On the other hand, the reactions between the antiserum produced by the Mulford preparation and the beta antigen was very much stronger than was the reaction between the antiserum produced by the ammonium hydroxide preparation and the beta antigen. From this observation, it seems quite definite that the ammonium hydroxide preparations contain a greater quantity of alpha crystallin (or act as a better alpha antigen) than does the Cecil preparation, whereas the Cecil preparation contains a greater quantity of beta crystallin (or acts as a better beta antigen) than does the ammonium hydroxide preparation. The results of this comparison are shown in table 5.

THE PREPARATION OF SEROLOGICALLY PURE FRACTIONAL ANTIGENS

Attempts were made to separate the alpha and beta fractions by other methods, such as precipitation with ammonium sulphate, but without success. We returned finally to a modification of the Hektoen-Schulhof method, which in the main is the Wooldridge method for the separation of nucleoproteins. The modification we employed was the precipitation of the alpha and beta fractions at their iso-electric points. The iso-electric point of a protein is the point at which it is neither acid nor alkaline, and this is the point of minimum solubility. The iso-electric point will vary for different colloids and proteins. The iso-electric points of the alpha and beta fractions were determined as follows:

An ammonium hydroxide extraction of lens protein was prepared in the manner before described, and filtered to clarity; 20 cc. of this solution was then placed in each of a number of beakers. To each beaker was added an increasing number of drops of tenth-normal acetic acid. As the number of drops increased in the different beakers an increasing turbidity was noted, until at the addition of about six drops the maximum precipitate appeared to occur. The p_H of each beaker was determined by using the La Motte 3-B outfit. (In making the determination it was necessary to fill the shells completely with the clear supernatant fluid.)

It was found that the maximum precipitate occurred at a p_H of from 5.2 to 4.8. Alpha antigens were now prepared by precipitations of whole lens protein at various hydrogen ion concentrations from p_H 6.0 to p_H 5.0. Alpha antiserums were prepared by injection into rabbits of those various alpha antigens. It was found that the maximum alpha antiserum-beta antigen reaction of these serums occurred in the alpha antiserums produced by alpha precipitated at p_H 6.0, but the reaction was still present in the alpha antiserum produced by alpha precipitated at p_H 5.0. The repetition of this experiment, and the examination of the antiserums produced by the injection of an alpha antigen precipitated at different p_H levels, finally showed that the iso-electric point of beta crystallin lay in the region of p_H 6.0 and of alpha crystallin from p_H 5.0 to p_H 4.8. Apparently the addition of tenth-normal acetic acid to the alkaline preparation of whole lens protein results in the precipitation of a small amount of beta in the neighborhood of p_H 6.0. As the p_H approaches 5.0, the precipitation of the alpha fraction becomes marked, while the precipitated beta tends to go back into solution. Further, after a p_H of 4.8 is reached, buffer action on the part of the precipitated alpha becomes evident, and over night the p_H will rise from 4.8 to 5.8. For this reason, when p_H 4.8 is first reached, a definite excess of acid can be added without further changing the p_H, and this step holds the p_H constant at 4.8. When acid is added beyond this point, however, carrying the p_H on the acid side beyond p_H 4.8, the turbidity of the solution grows less, the p_H now having passed beyond the iso-electric point of the alpha crystalline, which begins to go back into solution. We have availed ourselves of these observations to separate the alpha and beta fractions in a serologically pure state.

In practice, the method[10] is as follows:

The whole lens preparation is prepared as before described. Twenty cubic centimeters is placed in a number of tubes, and tenth-normal acetic acid is added until the maximum precipitate is obtained. The p_H of this tube is 4.8. Acid is further added until there is the faintest increase in turbidity of the supernatant fluid, indicating that the alpha is going back in solution. Thus the point is determined at which the maximum amount of acid possible may be added without redissolving alpha. The p_H is still 4.8 The quantity of acid to be added to the main bulk of whole lens protein is now calculated and added, the p_H again being checked. This should still be p_H 4.8. The mixture is allowed to stand over night. The precipitate is removed by centrifugalization. The supernatant fluid is practically pure beta crystallin, and the precipitate is alpha crystallin.

Further Purification of Alpha.—The precipitate is now dissolved in water, and tenth-normal ammonium hydroxide is added to a p_H 7.4. This is now dialyzed twenty-four hours to remove the excess ammonium hydroxide and is passed through a Berkefeld filter. Tenth-normal acetic acid is now added in the manner described before to a p_H 4.8; the alpha is again precipitated and removed by centrifugalization. This step is repeated until the supernatant fluid from centrifugalization gives a negative reaction to the ninhydrin test. Two more precipitations are now done. The final solution is sterilized by filtration. It is now cultured aerobically and anaerobically for seven days. After negative cultures, it is tested for serologic purity by precipitin tests against pure alpha and beta antiserum and by injection into rabbits, which should produce an alpha antiserum which does not react with beta antigen.

Further Purification of Beta Antigen.—The supernatant fluid from the first acetic acid precipitation is dialyzed in a collodion bag until the p_H of the surrounding tap water is reached. Twenty cubic centimeter samples are now placed in a series of tubes. Tenth-normal acetic acid (to precipitate any remaining alpha) is now added to these tubes in varying amounts to determine the maximum amount of acid which can be added without re-solution of any precipitate that may occur. This is again at about p_H 4.8. The total amount of acid necessary to add to the original bulk is calculated and added. The precipitate is removed by centrifugalization and discarded. Again the supernatant fluid is dialyzed, and this step is repeated until the addition of acid does not give a precipitate below p_H 5.6. The antigen is now tested against a pure alpha and beta antiserum. There should be no reaction to alpha and a good reaction to beta antiserum. The beta antigen thus produced contains only about 0.1 per cent protein by test. Accordingly, to facilitate immunization of animals, we have concentrated it as follows: The beta solution is saturated with sodium chloride and tenth-normal acetic acid is added to p_H 5.0. A heavy precipitate occurs (sodium chloride action on beta antigen—the sharpness of the iso-electric points being dependent on the absence of electrolytes). This precipitate is collected by centrifugalization at high speed for fifteen minutes, and the bulk of the precipitate measured. For each cubic centimeter of precipitate, 1 cc. of tenth-normal ammonium hydroxide is added, and as little water as is possible to manipulate. A slightly turbid solution results. This turbidity can be removed by centrifugalization; the excess of sodium chloride is removed by dialyzation, and the end-product sterilized by Berkefeld filtration. The resulting solution is beta crystallin in about 3 per cent concentration.

Table 6 illustrates the serologic purity of the fractional antigens thus produced.

Table 6.—*Serologic Purity of Fractional Antigens*

Antiserums	Antigen A 21.5	B 21
A 7 B 3 1 (antigen A 21.5)..........	Positive 100,000	Negative
B 56.2 (B 15.11 antigen)............	Negative	Positive 50,000

ORGAN SPECIFICITY AND SPECIES SPECIFICITY

The fractional antigens produced by this method show the same properties of organ specificity and lack of species specificity first pointed out by Uhlenhuth as a property of whole lens protein.

The alpha and beta antiserums produced by the injection in rabbits of beef alpha and beta crystallins react respectively with the alpha and beta antigens prepared from swine lenses as well as with beef alpha and beta crystallins. This organ specificity of the alpha and beta crystallins is shown in table 7.

The antiserums produced by the injection in rabbits of beef alpha and beta crystallins do not react with other bovine tissue antigens. They have been tested both against beef blood serum antigen and against beef aqueous antigen, and do not react. An antiserum produced by the injection of beef aqueous into a rabbit, on the other hand, reacts to both beef aqueous and beef serum, but not to any lens antigens, illustrating again the immunologic isolation in the normal eye of lens protein even from such neighboring fluids as the aqueous. Table 8 shows these reactions, illustrating the lack of species specificity of the crystalline lens, and of its fractions, alpha and beta crystallin.

---

[10] The methods of preparation of iso-electric points, mentioned below, are for bovine lenses. Experimentation with the lenses of other species has shown that the iso-electric points of alpha and beta crystallins may vary in different species, but in other animals differential precipitation of the alpha and beta crystallins at their iso-electric points is possible.

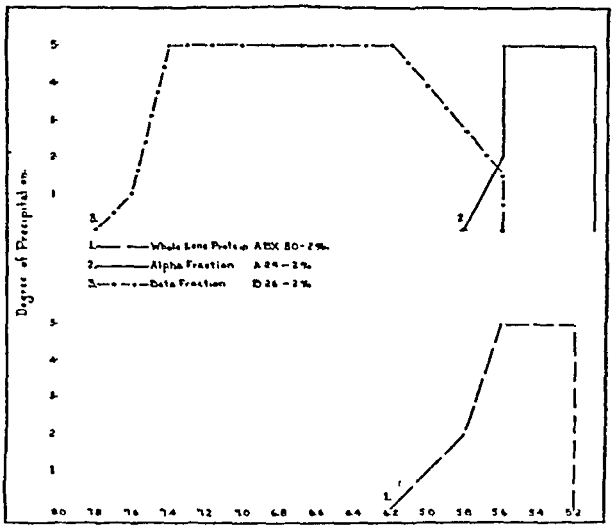
COMMENT

By the methods of preparing pure fractional antigens here outlined, pure fractional antigens have been obtained whose antiserums do not show cross precipitation when tested against heterologous fractional antigens which are relatively fresh. The alpha and beta antigens are, however, not equally stable. The alpha antigens have been preserved for many months, and the first pure antigens prepared are still stable and do not show evidence of precipitation. This is not the case with the pure beta antigen. Freshly prepared beta antigen produces a specific antiserum, which reacts strongly with the beta antigen and does not react with other antigens. Beta antigen, freshly prepared, shows no tendency to nonspecific precipitin reactions with heterologous antiserums, and does not give a precipitation with a hetero-immune serum even after twenty-four hours' incubation. After a period of a few weeks, however, the beta antigen becomes unstable, even when kept in the refrigerator. There develops a definite tendency to spontaneous precipitation as the antigen grows older. Likewise, after some weeks, the beta antigens begin to show nonspecific cross precipitation with other hetero-immune serums. However, if alpha antigen is mixed with the beta antigen, the beta antigen loses this tendency to spontaneous precipitation, the alpha fraction having apparently a protective colloid action against the spontaneous precipitation of the beta. The accompanying chart shows graphically this protective colloid action by alpha on the precipitation of beta. The pure isolated beta antigen has a definite tendency to precipitate spontaneously between p_H 7.8 and p_H 6.2. This is shown on the first curve of the upper figure, while the second curve of the upper figure shows the range of acid precipitation possible in the pure alpha crystallin. The lower curve shows the range of possible acid precipitation of whole lens protein, the mixture of alpha and beta protein, precipitation being possible only between p_H 6.2 and p_H 5.2. In a mixture of alpha and beta crystallins, the beta protein in the mixture does not show any tendency to spontaneous precipitation in the higher ranges from p_H 7.8 to p_H 6.2, where it does tend to precipitate when in a pure condition. Apparently the presence of the alpha antigen has an inhibitory effect on spontaneous precipitation on beta antigen between p_H 7.8 and p_H 6.2.

Table 8—*Species Specificity of Crystalline Lens*

	Antigens				
Antiserums	Alpha Crystallin (A 16 11)	Beta Crystallin (B 17.11)	Whole Lens (ABX 17.7)	Beef Aqueous (4)	Beef Serum (1)
Alpha (72 3)	Positive 30,000	Negative	Positive 30,000	Negative	Negative
Beta (74 3)	Negative	Positive 30,000	Positive 30,000	Negative	Negative
Whole lens 8990 4 .	Positive 30,000	Positive 30,000	Positive 30,000	Negative	Negative
Beef aqueous humor (52 4) .	Negative	Negative	Negative	Positive 1:32	Positive 1:10,000

This tendency of beta crystallin to precipitate spontaneously is of great interest, as it offers quite a plausible hypothesis to explain the etiology of senile cataracts. Beta crystallin does not tend to precipitate from whole lens protein, the alpha fraction having, as before noted, an apparent protective colloid action that prevents the precipitation of beta. Jess has noted that in old age and in cataractous lenses the quantity of alpha in the lens protein is greatly decreased. It seems plausible to assume that these facts may in some way be related to the causation of senile cataracts. The gradual decrease in the alpha fraction allows the beta fraction to become greater and relatively more pure, and further gradually removes a protective colloid action against spontaneous precipitation of beta crystallin. Thus a condition may be approached where beta crystallin predominates in the lens protein and the protective action of the alpha fraction, which normally prevents spontaneous precipitation of beta, is removed. Spontaneous precipitation of beta in vivo and in situ may now occur, with the resultant clouding of the lens. This is an especially interesting hypothesis when it is considered that the range of spontaneous precipitation of the beta fraction lies in the normal hydrogen ion concentration of the body fluids. Such a theory is, however, totally without experimental proof in vivo.



Range of precipitation of whole lens protein and alpha and beta crystallins at different hydrogen ion concentrations.

Lens protein contains both globulin and albumin. The question whether the albumin and globulin bear any relationship to the alpha and beta fractions naturally arises. No such relationship can be demonstrated. Globulin is present in ten times the amount by volume than is the albumin. Both the globulin and the albumin fractions react with antialpha and antibeta serums, indicating the mutual presence of alpha and beta fractions in both the globulin and the albumin.

At present a statement cannot be advanced as to the relative merits of the Cecil commercial preparation and the ammonium hydroxide preparation we have devised. The chemical analyses show little difference in the nitrogen content, and immunologic tests in vitro indicate that the Cecil preparation contains a greater relative quantity of beta crystallin, while the ammonium hydroxide contains a relatively greater amount of alpha fraction. Should further study show that anything is to be gained by a relatively greater quantity of either the alpha or beta fraction, one or the other methods of preparation of whole lens may then become preferable. A study of clinical hypersensitivity to lens protein is now in progress. The few observations already at hand indicate that a marked difference may exist in the skin reactions produced by these two preparations.

SUMMARY

A study of the preparation, and immunologic and chemical properties of whole lens protein, and its alpha and beta crystallin fractions, has been undertaken. New methods for the preparation of whole lens protein have been devised. These new preparations contain a larger relative amount of alpha crystallin and less beta crystallin than did the older preparations. It was found impossible to produce serologically pure fractional antigens by the methods outlined by other investigators. A method of preparing serologically pure alpha and beta antigens was then devised by which such pure antigens can be prepared with definite regularity. The basic point in this method is the utilization of the iso-electric points of the alpha and beta crystallins.

Study of these serologically pure fractional antigens shows that they are organ specific and not species specific, thus supporting Uhlenhuth's observations.

The pure beta crystallin fraction shows a tendency to spontaneous precipitation within the normal hydrogen ion range of body fluids. The presence of alpha crystallin prevents this spontaneous precipitation. This observation, coupled with the earlier observations of other investigators, makes possible an attractive hypothesis concerning the etiology of senile cataract.

ABSTRACT OF DISCUSSION

Dr. Zenas H. Ellis, New York The study of the nutrition of the crystalline lens is most difficult. But it is only through such thorough-going research as Dr Woods has done in studying the chemistry and immunology of the constituents of lens protein that we can hope to make progress in endeavoring to find the cause of the formation of lens opacities. Dr. Woods has given us a positive method of obtaining pure alpha and beta lens antigen and has shown that, like lens protein itself, they are organ specific Jess has shown that during the growth of the lens all through life there is a slow shifting of the quantitative proportions of the albumins. The two crystallines (water soluble) are the main proteins, albumin being present only in traces. In old age there is an increase in albuminoids. Jess also has shown that in cataractous lenses the quantitative proportions of the soluble albumin and albuminoids are greatly changed and that the lenses decrease in weight because of an enormous loss of fluid and a considerable loss of albumin. The loss of albumin is at the expense of the crystallines, while albuminoids showed a definite increase. This leads one to believe that the crystallines change over into albuminoids. Dr A. E. Davis at the International Congress of Ophthalmology in 1922 and at the American Ophthalmological Society in 1924 reported that he had arrived at a cataract preventive or cure without resort to surgery. Ninety-three per cent of the cataracts had responded favorably to his treatment. Working with the preparation introduced by Dr. A. E. Davis, we could not confirm his results, for no absorption of lens opacities was shown in any of our cases.

Dr. S. R. Gifford, Omaha: This section owes Dr. Woods and Dr. Burkey a great deal of thanks for the unbelievable amount of work they have done in perfecting a method of preparing a pure lens antigen that can be preserved Some work that we have been doing this year with another lens preparation compared to some work that we did a few years ago shows the immense importance of having a pure and standard lens antigen containing whole lens protein. One thing that ought to be borne in mind is that none of the work which has been done on the lens protein as a diagnostic agent or as a therapeutic agent has, to my mind, received sufficient scientific proof so that it can be accepted I was glad to hear Dr. Ellis report a series of cases in which he had tried out the lens treatment and recorded accurate results It must be remembered that this is all on an experimental basis and not to be treated otherwise until we know more about it.

Dr A E Davis, New York: The lens antigen that I first brought out was called by Dr Woods the Cecil antigen and the Mulford antigen, whereas the Cecil antigen and the Mulford antigen are exactly the same; in fact, it was my own invention At first I used this remedy in a suspension, but, of course, that could not go to the general public Dr Cecil and I then devised this method of making it sterile, and by the way, being a sodium chloride preparation, it went through the filter very well indeed In making the comparison of the original antigen and the ammonium hydroxide antigen, the protein element in the original antigen is considerably higher than in the other, and I think for that reason, having that additional amount of protein, it would be more efficacious in the treatment The original antigen also is much less irritating locally to the patient than the newer preparation This is another point that I am sorry Dr Woods did not carry out in his paper Of course it takes time for all these experiments The point I refer to is the precipitin titer. In my original cases, for the first fifteen cases that I reported, we bled all these patients and took this precipitin test However, the tests were not very satisfactory. I am in favor of using the whole protein of the crystalline lens, that is, not using the fractional elements of the protein separately Dr Woods has shown that the alpha fraction holds the beta fraction in solution so it does not precipitate; and this is a great advantage indeed With Dr Ellis, I am of the opinion that if we make further studies of the nutrition of the lens, if we can find that specific affinity which they claim that the receptors of the individual lens cells have for nutrition (and Dr Wheeler and Dr Kirby have started on that line), then, if in addition we can get an antigen that is stable and sterile, we shall come nearer to solving the problems of the nonoperative treatment of cataract While my own results are not quite so good, after being under observation for longer periods of time when the first reports were made, they show from 70 to 80 per cent of the cases arrested completely, and about 50 per cent of the cases show improvement in vision.

Dr I S Tassman, Philadelphia: It was my original purpose to speak of the work of some of the earlier investigations into this subject, by way of stressing the importance of the changes taking place in the soluble crystalline of the lens, during cataract formation Dr Ellis has gone over the later work of Jess About 1910 the cystein reaction was described, by which the proteins, in the presence of certain cystein groups, produced a red color by the addition of a few drops of a 4 per cent solution of sodium nitroprusside and ammonia. W Reiss, in 1911, and a little later Jess, demonstrated the regular occurrence of this reaction in normal human and animal lenses Jess then showed that the reaction was produced by the alpha and to a greater extent by the beta crystallins, and that the reaction was negative in senile cataract, the degree depending on the extent of the cataract formation Then when it was found that there was a decrease of the total proteins of the lens in cataract, solely through the two crystallins, it appeared that the absence of this cystein reaction in senile cataract depended on the loss of the cystein-containing fractions. There is no doubt about the presence of the reaction as demonstrated by the positive red coloring produced in normal lens with the addition of the 4 per cent sodium nitroprusside and ammonia, and its total absence in a hypermature senile cataract. The importance attached to the changes in the alpha and beta crystallin taking place during senile cataract appears to be supported by the work of Dr. Woods, when he showed how the beta crystallin, in particular, was affected in his experiments.

Dr. Alan C. Woods, Baltimore: I shall first answer Dr. Davis' comments. The Mulford Company was the source of our information that Cecil was the deviser of the present antigen made by them, and it was for that reason that I referred to the "Cecil" antigen. It was not until Dr. Davis called my attention to it by letter that I was aware he had suggested this method to Dr. Cecil. As Dr. Davis stated, the Mulford antigen has a slightly higher protein content. The protein content of the ammonium hydroxide preparation can be increased by decreasing the amount of solvent used. We used this proportion arbitrarily because it gave us roughly a preparation similar to the Mulford preparation. The objection to the Mulford preparation is that it seems to give false positives in skin hypersensitivity tests, whereas my own antigen gave negative reactions. In these patients skin tests with beef serum and beef aqueous were positive. It looks as though by skin tests which are more sensitive than the precipitin test in vitro there may be some species specific impurity in the Mulford antigen. For that reason, I have been using the ammonium hydroxide antigen. What Dr. Davis said about the irritability is quite true, but in this paper I specifically omitted saying anything about the use of lens protein in clinical patients. I referred simply to the ear vein in a rabbit. In the skin of a patient there seems to be no difference in the amount of irritation; in fact, the ammonium hydroxide may be less irritating. Both of them are irritating, however. Dr. Davis spoke of the absence of precipitins in man. I would not expect precipitins in the blood serum of a 150-pound man from an injection of a few cubic centimeters of 1 per cent protein. I should not expect to get antibody reaction in a man unless much larger doses were used. As far as the antibody reaction produced by the fractions goes, there is a radical difference. The antibody reaction to alpha crystallin is rapid and prompt, and to beta crystallin is slow and uncertain. If (and I say advisedly *if*) the immunologic energies of lens protein have anything to do with cataract, I should be much more suspicious of the beta fraction than of the alpha fraction, because the alpha fraction seems a bit more nonspecies specific than the beta. Dr. Tassman spoke of the balance of these two proteins in the lens, which is one of the most interesting things we have encountered. The interactions of alpha and beta are remarkable. For instance, alpha is precipitated by acid, beta is not. But if an excess of electrolytes is added to the solution of beta, it will be precipitated by acid. Alpha from whole lens protein can be precipitated by the use of sodium chloride, and thus very little beta can be precipitated. But if sodium chloride is added to a pure alpha solution, alpha is not precipitated. I do not know why. Very slight differences in the calcium concentration of the solutions cause most remarkable precipitations. If calcium is added slightly over the normal physiologic limits, changes occur in the turbidity of the solution. I do not know why. We have at least been able, now that we have pure antiserums, to test out these precipitates, to find out what we are dealing with, and to have a method of identifying our precipitates.

Loose Bodies in Joints.—The knee joint cavity is divided into five distinct but intercommunicating compartments—three in front and two behind. These are the suprapatellar pouch and the anteromesial, the anterolateral, the posteromesial and the posterolateral compartments. Each pouch allows of separate exploration through a relatively small capsular incision. A loose body originating in one of the anterior compartments finds a free passage from one to another, but does not ordinarily make its way into a posterior compartment, as the connecting path is somewhat circuitous. Free communication between the two posterior pouches is, for practical purposes, blocked by a midline synovial partition connected with the posterior crucial ligament.—Platt, Harry, *Brit. M. J.*, May 28, 1927.

THE RELIEF OF ITCHING BY EPINEPHRINE IN CERTAIN CASES OF INFANTILE ECZEMA[*]

J. D. PILCHER, M.D.
CLEVELAND

Every one who sees infants with eczema appreciates the extreme suffering they frequently manifest. The infant himself may not only rest and sleep very little but his constant fretting and crying deprive the other members of the family of their rest, so that it is not uncommon to have a mother state that she has not slept for weeks or even months, implying, of course, that she has had no uninterrupted restful sleep during that time.

One morning an infant in the hospital ward suffering from a severe form of eczema freed himself from restraint and manifested every evidence of extreme discomfort; he was given epinephrine intramuscularly; in two minutes he was quiet and in three minutes was asleep and slept for more than an hour. During the rest of the morning he seemed comfortable; the best he had been in the hospital, one of the attendants remarked.

Since this experience I have usually seen the subjects in the hospital with eczema when they manifested discomfort, and if the discomfort seemed sufficiently severe and to be due to the eczema epinephrine has been administered subcutaneously or intramuscularly and the observation continued at least fifteen minutes.

During the past two years seven such infants have received something more than twenty injections and relief was manifested from about three fourths of them. Several times also the nurses on night duty found that relief was obtained and sleep followed the use of epinephrine. The relief is usually striking, is noted promptly, often within two minutes, just as it is in urticaria, and may persist for an hour or more, and not infrequently the patient falls into a restful sleep. These infants were from 5 to 14 months of age; five of them were of the vigorous, well nourished type in which eczema is so commonly seen; two of them were somewhat undernourished. A 30 month old boy with a severe generalized eczema of long duration, so that the skin was dry and much indurated and in numerous places infected from continuous scratching, seemed to be unaffected by several epinephrine doses. A sister, 6 months old, however, in the hospital at the same time, was favorably affected by epinephrine.

A much larger number of subjects with less marked eczema did not receive epinephrine because it was thought that their suffering from skin irritation was not sufficiently severe to enable us to be certain whether or not the epinephrine would be effective.

CONTINUED USE OF EPINEPHRINE

Five infants of this group received epinephrine every three or four hours hypodermically or intramuscularly during the day for from two to twelve days and occasionally at night when indicated. It seemed that they were more comfortable than during the days without it. One intelligent mother remarked that she had never seen her infant so comfortable as when he had epinephrine.

EPINEPHRINE BY MOUTH

Although it is usually held that epinephrine does not show physiologic effects when given by mouth, the literature contains reports of a certain number of adults who have reacted to the administration in this manner, notably by a considerable rise in blood pressure. For this reason in three subjects epinephrine was given by mouth every three or four hours during the twenty-four hour day for several weeks without appreciable effect on the course of the disease, either by lessening the evidence of irritation or by shortening its course. A considerable number of dispensary patients, also infants, have been given epinephrine by mouth, without conclusive results; for while several mothers thought that their infants, at times, showed less discomfort with its use, other mothers did not, and the natural course of eczema even without treatment is so variable that no credence at this time should be placed in these results. The average dispensary patient, too, is unsuitable for critical study of this kind, for one cannot know whether a drug is given at home, so for this reason only those cases are reported that were observed in the hospital.

---

[*] From the Babies' and Children's Hospital and the Department of Pediatrics, Western Reserve University.

DOSAGE

The hypodermic dose was from 0.1 to 0.3 cc. of the 1:1,000 solution, seldom more than 0.2 cc., however. This is somewhat large in comparison with the usual adult dose, but harmful results were not seen. Occasionally pallor of the face and extremities (from vasoconstriction) was noted, of but a few minutes' duration without other signs of toxicity. It is my impression that the relatively large dose is necessary for effective results. The infants varied somewhat in their reaction to epinephrine, for instance one of 9 Kg. weight was relieved of its suffering with 0.15 cc. and became quite pale with 0.2 cc., while a 5.5 Kg. infant of about the same age required 0.2 cc. for effective results and showed pallor only with 0.3 cc.

COMMENT

Infants with eczema, just as do other infants, cry and fuss from causes other than skin irritation. A number of times very restless, squirming infants were not quieted by epinephrine but became quite happy on receipt of a bottle. On the other hand, in one instance an infant was very restless and uncomfortable at feeding time, and would take neither her mother's breast nor complemental bottle, but became quiet with epinephrine and nursed well. In the presence of a mother who for weeks had taken her infant in arms at every whimper, epinephrine was not effective on one occasion but was so at other times after the mother had been persuaded to remain away from her infant.

No reference has been found in the literature to the use of epinephrine against itching in infantile eczema. Holländer[1] noted marked decrease in the itching and discomfort in three cases of eczema and in other skin lesions associated with itching in adults. The epinephrine was given subcutaneously, by mouth and in an ointment.

Ephedrine gives relief in many cases of asthma. As it is usually effective by oral administration, it is suggested that it be tried in suitable cases of eczema. We have nothing to report at present.

CONCLUSIONS

From these results it appears that epinephrine subcutaneously or intramuscularly gives temporary relief from the severe discomfort of certain eczematous infants as it does in urticaria. Sufficient data are not at hand to warrant an opinion as to whether it is otherwise beneficial in eczema, further than that its sedative action lessens the effect of the trauma from the scratching.

Clinical Notes, Suggestions and New Instruments

UNUSUAL COMPLICATION FOLLOWING A LOW CESAREAN SECTION *

Alice F. Maxwell, M.D., San Francisco

A. V., a Greek woman, aged 27, a multipara, seen in the outpatient department of the University of California Obstetrical Service in the seventh month of her second pregnancy, had been delivered of her first child seventeen months previously by cervical section, by an experienced obstetrician, after some hours of labor. A cephalopelvic disproportion was the reason for section. Her convalescence was uneventful, and she was discharged after thirteen days.

The pelvic measurements, physical examination and pregnancy were normal, but the patient was advised to report to the hospital with the onset of labor pains. In general, it has been the policy of the department not to permit a patient to attempt natural labor after a previous cesarean section.

Labor began late at night, just at term, but the patient did not enter the hospital until four hours had elapsed, at which time the pains were coming every three minutes and were nonexpulsive in character. The membranes had not ruptured, and there was no hemorrhagic discharge. No rectal or vaginal examination was made, and she was immediately prepared for a laparotomy. Within an hour the patient was catheterized and anesthetized; the old scar extending from the umbilicus to the symphysis was excised and the abdominal cavity entered. A few omental adhesions to the former midline incision were readily freed and the lower portion of the uterus presented. Much to my surprise, a fair sized hematoma about 3 inches (7.6 cm.) in diameter was found under the peritoneum at the vesico-uterine junction. The peritoneum was excised at this point, and the blood clot removed, which showed that the bleeding was coming from a rent in the uterus just behind the bladder. The rupture was about 2 inches (5 cm.) long, running in a longitudinal direction, and a finger was passed through the separation directly into the lower uterine cavity. There was no difficulty in separating the bladder off the uterus, enlarging the incision through the rupture and delivering the child.

An 8 pound (3.6 Kg.) baby girl was delivered in good condition. The mother made a rapid recovery, and was discharged on the fourteenth day.

TREATMENT FOR ACUTE TRAUMATIC HEMATOMA OF EXTERNAL EAR

Harry A. Britton, M.D., Ithaca, N. Y.
Athletic Physician, Cornell University

This condition, which is common among boxers and wrestlers and is less frequently found among men engaged in other sports, responds as a rule to a very simple treatment. During the last five years I have had the opportunity to treat about 100 cases, and in all of these I have obtained good results. I feel that I can promise a perfect ear if instructions are followed.

The treatment consists first in aspirating the blood or serum which is present and then applying pressure to the anterior and posterior surfaces so as to place and keep the surfaces once separated by the fluid in apposition. Aspiration can be done immediately or at any time within five days after the date of injury. This pressure should be applied for six or seven days, and can then be safely removed. To get the best results the ear should be carefully protected, and not be injured even slightly for about two weeks after treatment; otherwise, some thickening is apt to occur. In wrestlers it is often impossible to stop them from practice for a period of a week or more, so I make no promise that they will get a perfect ear. I usually tell them they are liable to have some thickening. In a number of cases, however, this thickening has been so slight that it is not noticeable except to those who know about the injury.

The method of applying pressure varies considerably. If the hematoma occurs along the edge of the ear, i. e., in the fossa of the helix, I cover a piece of number 18 copper wire with adhesive tape very evenly, bend it so that it fits the fossa perfectly, and then by small pieces of adhesive tape draw the edge of the ear firmly over the covered wire This I always remove during wrestling practice Recently, I took a small piece of felt instead of wire and fastened it in the fossa with a very good result

When the hematoma is in the concha or in the fossa of the antihelix I fill these parts with plaster of paris and apply pressure by the use of the copper wire, making a loop on each end, covering these loops with adhesive tape, and then bending the wire so that one loop is pressing on the plaster cast and the other on the back of the ear This should be left on for a week The amount of pressure applied is just enough to be felt If pressure is made too great the ear will become tender, and a raw surface will develop as a result of pressure necrosis

If the patient wishes to continue with his sport, I often use thick collodian and cotton instead of the plaster of paris, packing it in firmly, allowing it to dry and then applying the wire as described I remove the wire whenever the patient wishes to practice, however, and reapply it as soon as practice is over I do not consider this method ideal but I have been able, with its use, to carry several boys through the wrestling season with little or no deformity

I have not found aspiration in itself to have any value, and I believe that the success of the treatment depends on the proper application of pressure after aspiration I aspirate all hematomas whether small or large, having obtained as little as 0 1 cc and as much as 5 5 cc

Prevention of this condition however, is even more important than its treatment, and a very effective scheme for prevention is to pad the ears front and back with cotton and then bind them close to the head with a band of adhesive tape 1½ inches wide by 30 inches long Protected in this way, a wrestler may safely withstand considerable 'roughing" as far as his ears are conerned

DIPHTHERIA A CASE OF LABORATORY INFECTION *

Robb Spalding Spray, Morgantown, W Va

Numerous references to laboratory infections with plague, typhoid, tularemia and other diseases may be found in past and current literature Similar references to diphtheria, however, seem to be quite uncommon The instance presented here of a clear-cut laboratory infection, establishing a definite incubation period peculiarly supported by a control, would appear to warrant a brief report

In a class in medical bacteriology a strain of the diphtheria bacillus was given out for cultivation, Tuesday, April 19, 1927 This strain was isolated three years ago during a local epidemic from one of a family in which four severe cases developed Its toxicity has been repeatedly demonstrated by death of inoculated guinea-pigs within three days

Cultures were given out on Loeffler's serum with considerable condensation water on the slants During the course of the hour one student reported that the tube from which he inoculated had been tilted and the cotton plug wetted, and that on flaming the plug and shaking to extinguish the flame he had spattered his face We at once required him to wash his hands with 5 per cent phenol (carbolic acid) and his face with mercuric chloride, followed by hot water and soap This man who may be considered a "control," remained well

On Friday another student was absent from class, and it was reported that he had a "sore throat" On Saturday at noon a throat swab was submitted from him by a local physician, who reported a definite membrane, pulse rate 120, and temperature 100 5 F Direct examination revealed numerous spironemas and fusiform bacilli, giving a definite suggestion of Vincent's angina, but there were also observed numerous slender bacilli of diphtheritic morphology, except that granules were not sharply defined with either Neisser's or Albert's stain However, in view of the history and the toxic condition, 10,000 units of antitoxin was given intravenously without awaiting further report On the following day Loeffler's serum culture showed a profuse growth of a typical slender granular diphtheria bacillus, identical in morphology with the laboratory strain A pure culture was isolated, and a guinea-pig inoculated with this strain died in less than ninety hours

The patient stated that within three hours of the administration of antitoxin his temperature and pulse rate dropped, and the toxic symptoms had practically disappeared Within twenty-four hours the soreness in the throat subsided and the membrane faded He made a prompt and complete recovery, and two negative cultures were obtained on the eighth and ninth days from the date of injection of antitoxin, on which he returned to class Questioning revealed that this student had the same experience as the "control," but regarded the matter lightly and did not report the incident or take any prophylactic precaution It may be of interest to note that the case has served to stimulate a healthy respect among the students for the subject of bacteriologic technic as applied to pathogenic bacteria

OTOMYCOSIS REPORT OF THREE CASES

P M Lewis, M D Memphis Tenn

I am prompted to report these cases because of a recent article[1] on otomycosis by Dr Joseph W Miller of New York

REPORT OF CASES

Case 1 —Mrs F aged 40, seen in my office, June 16, 1926, had never had any ear trouble until four days previously, when she noticed an itching and fulness in the right ear Examination showed a large whitish gray mass, completely covering the membrana tympani and the lining of the bony canal wall Strong irrigation dislodged the mass, which was like a cast of the drum membrane and inner canal wall It was definitely a fungus growth macroscopically, so microscopic examination was not made The ear was scrubbed out with 95 per cent alcohol and 2 per cent salicylic acid in alcohol prescribed for use at home There were no further symptoms and no recurrences

Case 2 —Mrs F M P, aged 26, referred by Dr Henry Watkins and seen, Sept 13, 1926, stated that the left ear had been stopped up for two weeks, and that there had been considerable itching and rather severe pain for the past two days Examination revealed a very large, yellowish white mass which filled the inner portion of the canal and covered the membrana tympani The same treatment as in case 1 was used with immediate relief of all symptoms Microscopic examination showed the growth to be a mold, *Aspergillus flavus*

Case 3 —G, a man, aged 20, seen, Oct 28 1926, stated that the right ear had felt stuffy for four weeks, had itched a great deal, and for the past week had been very painful Examination showed a dirty grayish mass covering the drum membrane and the anterior and inferior canal wall in its inner half The treatment used in cases 1 and 2 was employed with the same result Microscopic examination of the mass showed *Aspergillus niger*

COMMENT

Dr Miller states that his two patients had been using olive oil in their ears It is the usual teaching that oils or glycerin have been used in ears which develop otomycosis Bezold found that 75 per cent of all the patients he saw had been using them None of my three patients had ever had previous ear trouble They were all intelligent, educated people None of them had ever used a drop of any kind of oil or glycerin in their ears I questioned them particularly about this, as I had been taught that the use of oils was practically always responsible for fungi growing in ears It is now my belief that the history of oils having been used is a mere coincidence People have a deep-rooted conviction that oils and glycerin are very beneficial for ear ailments, especially if there is any pain or itching It is therefore obvious that a large percentage of patients with otomycosis will give a history of having used "sweet" oil or something of the sort in their ears

Why these fungi lodge and grow in some ear canals I do not know, but the diagnosis is extremely easy and the treatment very simple and efficacious.

[1] Miller, J W Otomycosis Its Relative Frequency, J A M A 88: 1077 (April 2) 1927

This case has been presented because it brings out several interesting and instructive features:

It is one of the few reported instances in American literature of uterine rupture occurring after a cervical cesarean section Indeed, the rarity of this complication after this type of incision has been emphasized as one of the advantages of the operation.

Our methods of judging the strength of the uterine scar and its ability to stand the strain of subsequent labors are not infallible. The history of an easy normal convalescence and discharge from the hospital within two weeks would suggest the absence of uterine infection at the first operation, with resulting good healing of the incision. Nor can the weakness of the scar be attributed to inexperience and poor approximation of the cut surfaces. The surgeon at the first operation was an experienced man and an enthusiastic advocate of the advantage of the low cervical incision.

All obstetricians recognize that low implantation of the placenta may impair and weaken the uterine wall The absence of this complication or any etiologic factor leading to weakness of the scar is significant.

Finally, this case serves to emphasize that a scar in the uterus, in either the upper or the lower portion, is not innocuous, and must be regarded as a factor of unknown strength Its integrity in subsequent labors cannot be determined by our present methods of diagnosis, and its potentialities to rupture must always be appreciated.

New and Nonofficial Remedies

PLASMOCHIN

Preliminary Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following statement. W A. Puckner, Secretary.

Plasmochin is a synthetic quinoline derivative, developed in Germany and proposed for use in the treatment of malaria For many years attempts have been made to find a substitute for quinine that would be cheaper, less bitter, less toxic and more specific than the natural drug Plasmochin appears at least to represent a step forward in this search though it is by no means a full solution of the problem of eradicating malaria. It is said to act by destroying some of the forms of the malarial parasite and by inhibiting the development of others.

Reports have been published on the use of Plasmochin in malaria produced in canaries, and some clinical trials have been reported. All of this work seems honest, efficient and well controlled. No overstatements or overenthusiasms appear anywhere, except possibly in the papers by Prof P. Muhlens of Hamburg. Professor Muhlens mentions cyanosis and gastralgia as toxic symptoms in man when large doses of Plasmochin are used But Dr P Manson-Bahr states (*Brit. M. J.*, March 12, 1927, p 466) that cyanosis, due apparently to the production of methemoglobin in the blood, may occur in some sensitive human beings *on a dose of the* drug less than that necessary to affect the malarial parasites Manson-Bahr also states that in man the effective dose of Plasmochin causes the appearance of urobilinogen in the urine for several days. All of the observers, both of man and birds, appear to agree that.

1. The new drug is most effective on the quartan forms of malarial parasite.

2. In tertian malaria a [illegible] of the new drug with quinine (in dosage of 0 01 [illegible] 25 Gm of quinine sulphate) is mo[illegible] alone

3. As shown by Dr. Roehl's work on bird malaria Plasmochin, in this animal, is sixty times more effective than quinine.

It should be pointed out that results derived from the study of bird malaria have chiefly a suggestive value, and that, in view of previous disappointing results from widely heralded new drugs, further clinical study must precede any really optimistic estimate of this drug's therapeutic value in human beings.

Plasmochin is manufactured by the I G Farbenindustrie Aktiengesellschaft, Germany In the German publications, Plasmochin is somewhat indefinitely stated to be an alkylamino-6-methoxyquinoline salt The Winthrop Chemical Company states that it has imported a considerable quantity of the drug in the form of tablets for clinical trial on a large scale by American investigators; the packages of these tablets bear as a synonym for Plasmochin the somewhat more definite chemical term, ethylaminoquinoline tannate. The Council asked the Winthrop Chemical Company to furnish a supply of the drug itself, so that standards which shall assure the identity and uniformity of the product may be established. The firm replied that it would endeavor to secure the requested specimen from the manufacturer in Germany, but that the product when placed on the market in this country will be manufactured here

The Council has authorized the publication of the preceding statement in response to requests for information regarding Plasmochin, and has postponed further consideration until clinical evidence concerning the efficacy, safety, and dosage of the product is available. The Council, however, at this time calls attention to the fact that the name chosen for the compound, Plasmochin, has a certain degree of therapeutic significance instead of indicating, as it properly should, merely the chemical composition of the product. A list of references to Plasmochin is appended.

Heart Block.—Recent advances in cardiology have confirmed the views, more than once expressed, that life is mainly threatened by myocardial conditions, and in these are included changes in the sino-auricular node, auriculoventricular node, and the bundle of His. . . . I need only briefly mention the two special nodes of tissue, the sino-auricular node close to the base of the auricles, also the auriculoventricular with *the bundle of His running down in the* myocardium and dividing into two branches, one for each of the ventricles The impulse to rhythmic cardiac contraction originates in the tissue of the sino-auricular node, and is transmitted by the muscular fiber of the auricular walls to the auriculoventricular node, and therefrom by the bundle of His to the ventricular walls. The heart is supplied by branches of the vagus and the sympathetic system of nerves; branches of both of these reach the sino-auricular node, also the auriculoventricular, while the substance of the cardiac muscle is capable of originating beats of its own When through disease the sino-auricular *node* ceases to function, the auricles pass into a condition of fibrillation, but the ventricles still continue to beat at a rate and with a rhythm special to themselves One of the results of alteration in the rhythmic discharge of impulses from myogenetic and cardiac nervous mechanisms is the occurrence of extrasystoles or of tachycardia An extrasystole is but a single contraction due to the impulse which produces it being discharged earlier *than* those normally emerging from the sino-auricular node "Heart block" is an irregularity of rhythm due to some defect in the auriculoventricular node, or the bundle of His, whereby impulses *from* the sino-auricular node are not conveyed to the ventricles, and as a consequence the ventricles commence to beat spontaneously —Oliver, Thomas: Heart Disease and Pregnancy, *Brit M J.*, April 16, 1927.

LIMITATIONS OF GOITER PROPHYLAXIS

Interference with the usual routine of life and activities of individuals is seldom popular in modern democratic governments. This is true in relation to the physical and mental health of persons as well as with respect to their working schemes and political doings. Consequently it is not easy to institute plans for human betterment of either a physiologic or a social character on any wholesale basis involving large or fixed groups of the population. The history of attempts at universal vaccination illustrates this. It crops out also in efforts at widespread physical examination. If these are made compulsory, they are likely to be regarded as an insult to personal liberty. Nothing short of education can overcome these inborn feelings; nor is it wise in a democracy to tolerate the subjugation of the individual except under circumstances that have a nearly universal appeal of wisdom and justice.

The relation of a shortage of iodine in the environment to the incidence of endemic goiter has become well founded.[1] Extensive data are now available to show that iodine is of wide distribution in minute traces and is more or less concentrated by the leaves of plants and the thyroid glands of animals. Goiter is due to a deficiency of iodine. In the words of a recent writer,[1] the history of the past century teaches most emphatically that the treatment of goiter is unsatisfactory and accomplishes little toward the control of the disease, but those attacking the problem from the standpoint of preventive medicine—physiologists, biochemists and public health authorities—have accumulated sufficient evidence to justify the assertion that endemic goiter is the easiest known disease to prevent. By further detailed study of the fundamental principles underlying the cause and prevention and with the constant application of scientific data by the state health organizations, we should, he concludes, see the fulfilment of an earlier prediction: Within another generation there will be no endemic goiter problem.

Until recently, so-called goiter surveys were largely concerned with regions for which a high incidence of the disorder was either known or suspected. There is ample reason for believing that proximity to the sea confers a comparative freedom from endemic goiter.[2] Not only are the food and drinking water obtained near the sea more likely to contain the iodine needed to prevent goiter, but the wafting in of ocean spray is believed by some to contribute measurable quantities of the requisite element. Moreover, the inclusion of sea food in the dietary undoubtedly aids in maintaining the equilibrium of the thyroid gland. The observation that endemic goiter is least frequent along the seacoasts apparently holds true, with minor exceptions, in America and in Europe; for the disease is most conspicuous in the interior of these continents. There are some exceptions, however, that indicate the real need of specific rather than generalized information for each district. The newer studies of some of the states on the Atlantic Coast furnish instructive evidence from which it is apparent that endemic goiter is present to a far less extent in Massachusetts than in certain states in the Great Lakes Basin. Moreover, the incidence of goiter is not uniform in Massachusetts, being least along the seacoast and greatest in the central and western portions. Connecticut presents similar features.

Because of the relatively slight incidence of thyroid enlargement in these states and the fact that a large majority of the involvements are of the minor type, the government experts[2] believe there is no reason for special preventive measures on the part of the state and local health departments. They do not see any necessity for universal prophylaxis such as may be attained by iodization of table salt or municipal water supplies. This advice is in accord with the position taken by The Journal and supported by such consultants as Plummer and Marine.[3] It will not be amiss to repeat the warning of Olesen and Taylor.[2] It should be remembered, they remark, that the treatment of endemic goiter is frequently disappointing. Especially should it be recalled that iodine, used in treating goiter, is a two-edged sword. When used injudiciously, either in improper doses or in certain types of goiter which are made worse by such medication, iodine may inflict irreparable harm. Only the well trained and experienced medical practitioner should undertake to treat existing goiters.

In localities, such as those referred to, where goiter does not become a problem for community prophylaxis, the responsibility of the practicing physician becomes all the greater. To him is shifted the more serious responsibility for the exceptional "few individuals" in a "few localities." Probably the period of pregnancy presents an outspoken instance for his consideration. An observer in this field has remarked that every survey or study emphasizes the importance of prevention during pregnancy. The relation of congenital defects to the adenomatous or tumor conditions of later life is being appreciated more and more with each careful study. The disappointments in our attempts to control or treat tumorous thyroids are known. Therefore, he adds, we cannot stress this point too strongly and in endemic goiter districts we need the attention of the physicians who educate and direct women through this important period, and of every prospective mother. According to Marine,[4] the administration of iodine, possibly to the extent of a milligram a day during pregnancy and lactation, would be an excellent physiologic procedure, whether the individual resides in a district where the incidence of goiter is high or in a district where the incidence is extremely low. Iodine would be beneficial in meeting the increased physiologic demands during these periods even though the natural supply of the element is always sufficient to prevent thyroid enlargement.

VACCINATION OF THE NEW-BORN AGAINST TUBERCULOSIS WITH BACILLUS CALMETTE GUÉRIN

The history of the vaccination of new-born infants against tuberculosis with Bacillus Calmette Guérin (abbreviated to B C G) since July 1, 1924, in France and other countries over a period of two and one-half years to Jan. 1, 1927, has just been reviewed by Professor Calmette with his co-workers Guérin, Nègre and A. Boquet at the Pasteur Institute in Paris. Indeed, the entire March issue of the *Annals of the Pasteur Institute*, consisting of 368 pages, is devoted to this subject. The vaccine is a living tubercle bacillus of bovine origin rendered avirulent for all animals by 230 passages on bovine bile medium. While the authors quote the reports of other workers and use these as reasons for suggesting the vaccination of new-born children with B C G, they depend chiefly on their own experimental work as the prime reason.

For the preparation of the vaccine, the B C G organism is transferred from the bile medium to a synthetic medium from which in about three weeks, when it has attained a full film and the living organisms are at the maximum, the clear underlying medium is removed by a pipet. A number of sterile glass beads and a small quantity of dextrose solution are then added to the flask in which the bacilli remain, and this, fastened on a brass plate operated by an electric motor, is slowly revolved for fifteen minutes, when the clumps of bacilli are broken and an emulsion of bacilli is obtained. The emulsion is then diluted with a solution of 1 per cent dextrose and 4 per cent glycerol in water and shaken until the whole quantity is such that 2 cc. contains 0.01 Gm. of the bacilli. The liquid vaccine is then placed in ampules of 2 cc., which constitutes a single dose to be fed to an infant in milk: Three successive 2 cc. doses are given to each infant with two days intervening between each dose; for example, the doses are given on the third, fifth and seventh days of life. Each dose is approximately 100 mg. by weight, or 400 million bacilli of B C G.

In France alone, up to Jan. 1, 1927, 21,200 children had been vaccinated. As many more in Belgium, Roumania, Greece, Algeria and Indo-China raise the total to 43,283 children. Out of this large number vaccinated, only 982 were suitable for statistical study by Moine and 1,050 by Biraud. The 1,050 of the latter's studies presumably included the 982 used by Moine and therefore may be taken as the maximal number so carefully recorded as to satisfy the statistician. For these, however, there were no control groups and both statisticians were compelled to compute control figures from general death rates and from reports of studies for other purposes and from other periods. They arrive at mortality rates from tuberculosis of 26 per hundred from tuberculosis dispensaries and 32.6 per hundred for all children under 1 year of age, Paris born and left in a tuberculous environment (p. 206). These figures are based on reports as far back as 1913, and for Stuttgart as far back as 1889. For the period 1924-1927, after years of intensive antituberculosis work they *do not* have mortality figures with which to compare their experimental statistics. There are almost no necropsy studies in the series of those dying. Another conclusion which a careful perusal of the figures forces on the reader is that vaccination not only lowers the mortality rate from tuberculosis but also lowers that from all other causes of death. It would seem that the care and education which precede and follow vaccination must render as preferred the group of children and families studied, and that the full truth is not evident from the comparisons drawn. It is a matter for regret that, in an experiment so far reaching and so extensive, care was not taken to secure control figures that might have made the published results more convincing.

Other features of the different papers are striking. In the first paper reference is made to the infection of the fetus by a so-called tuberculous ultravirus which traverses the placenta. This type of fetal infection is one explanation offered for the high death rate in the first year of life of infants born of tuberculous mothers, and it is used as one chief reason for vaccination with B C G in the early days after birth. The finding of Valtis (p. 211) and others that a new-born child already is infected with a potential living infection is contrary to the accepted views and, if found to be true in general, would be of far-reaching importance. It would, however, in a measure render necessary a reconstruction of the premise on which the proposed vaccination is based; for in such a case the child would already be potentially infected or possibly resistant to a reinfection. It would seem imperative that this question of the presence of a filtrable virus in the fetus of a tuberculous mother be determined by most careful work.

[4] Marine, David: The Importance of Our Knowledge of Thyroid Physiology in the Control of Thyroid Diseases, Arch. Int. Med. 32:811 (Dec.) 1923.

The question of tuberculin reaction in infants during the first year of life also forms a serious phase of the problem. The instructions accompanying the vaccine state that the tuberculin test should not be used, as it is of no value in infants under 1 year of age. But the authors state on page 208, "We already know by studies of the tuberculin reaction (Pirquet) that of every 100 children living in a tuberculous environment seventy-six are infected at the end of the first year." On page 257, however, Weill-Hallé, who alone seems to have followed his clinical studies with the care of scientific accuracy, finds that at the end of the first year in those vaccinated with B C G by ingestion 26.6 per cent of positive reactions develop in children born in a tuberculous environment and only (p. 258) 7.6 per cent in those born in a nontuberculous environment. At the end of two years the percentage of the vaccinated born in a tuberculous environment with positive reactions is 60, or a little more than double the number observed the first year, while of those in a nontuberculous environment the percentage with positive reactions is 28, or nearly four times as many as in the first year. A fair conclusion from these figures would seem to be that the ingestion of avirulent tubercle bacilli does not have great influence on tuberculin sensitiveness and, from our former knowledge, we could safely add, on infection with tubercle bacilli from the outside. Certainly ingestion of B C G does not produce skin sensitiveness in 100 per cent of those vaccinated in this way.

This is further substantiated by the work of Remlinger and Bailly (p. 288) in guinea-pigs, for none of these developed skin sensitiveness after ingestion of B C G and yet there were acid-fast organisms in the stools of these animals from the second to the twelfth day, which disappeared completely only after the sixteenth day.

In sharp contrast to this is the study by Weill-Hallé and Tarpin on a small group of children vaccinated subcutaneously with B C G. All these developed a skin sensitiveness to tuberculin in from two to three months; the determination of the exact time of its appearance was interfered with by the time of the return of the child to the clinic. In each case of the latter group, as in cattle and other animals inoculated subcutaneously, a tuberculous process of cold abscess was caused with resulting sensitiveness of the skin. Surely the only conclusion is that ingestion of avirulent tubercle bacilli does not as a rule create the condition which we have all believed to be the evidence of tuberculous infection—a tuberculin reaction.

This does not dispose of the question, however, of the persistence of tubercle bacilli in the intestines for a period of ten days in guinea-pigs (p. 288). Their very presence there, possibly multiplying, may create itself a surface or a general resistance to the invasion of bacilli of greater virulence or invasive power. From this standpoint, vaccination by ingestion may be of significance. Even if the evidence offered in these papers is not convincing at present it may possibly lead to new knowledge.

Guérin, Nègre and Boisière (p. 233) devote a paper to a cattle experiment but, while it is of economic interest, the method of vaccination is subcutaneous and is not therefore in the same category as vaccination of the new-born by ingestion of avirulent B C G.

This may also be said of the Dissé experiment with monkeys (p. 205). There was only one monkey vaccinated with B C G by ingestion alone and, while this is suggestive, further proof is required before it could be used as a basis for human vaccination.

These papers may be said to represent the culmination of the life work of a revered scientist. They may open a new era in the eradication of tuberculosis and in the knowledge of its epidemiology. For the United States, however, and for all countries it would seem wise to hold in check uncontrolled enthusiasm for its use until those charged with the responsibility of safeguarding the public have carefully proved that the method and the premises are sound.

THE CHANGING RECORDS OF MORTALITY

Viewed from an economic standpoint and stated somewhat bluntly, the value of the individual depends in considerable measure on the length of his life. National welfare, so far as it is an expression of possibilities of human performance, is inevitably concerned with the problems of mortality. The health and vigor of a race or group is a decided asset; ill health and its consequences are burdens imposed on the population. Students of civilization have inquired whether or to what extent it is actually necessary for the world to carry this "colossal load" of human misfortune. One can readily understand why every report of a better turn in the mortality trend is so heartily welcomed.

Indications from modern biologic investigations might lead to the conclusion that death is neither inevitable nor fundamentally necessary. The "immortality of protoplasm" is at once suggested by the modern study of tissue cultures. Cell masses kept alive outside the body, as in the experiments of Carrel of the Rockefeller Institute for Medical Research, have continued to multiply and grow apparently unchanged by time during more than a decade. This accomplishment has depended on securing a suitable external environment for the isolated cells. Woodruff's demonstration, at Yale University, of the uninterrupted reproduction of protozoan protoplasm without conjugation through several thousand generations of paramecia likewise raises the question as to the necessary interruption of existence. One can understand, then, why a modern imaginative writer[1] should have suggested that if one could at intervals thoroughly wash man free from his poisons and nourish him, there seems to be no reason why he should not live indefinitely.

On the other hand, there are plenty of indications of Conrad's reminder of the "faithful death that never forgets in the press of work the most insignificant of its children." Pearl[2] has argued that the potential duration of life is definite and unchangeable: it is a function of bodily organization. It is seen in all forms of life: after a certain definite period death is a natural consequence whether the living thing is a plant or an animal, invertebrate or vertebrate, cold blooded or warm blooded, bird or mammal. Rarely, however, is this full potential span of life realized: some environmental factor steps in to terminate life before its natural course is run.

From this standpoint, the problem of effective living and personal hygiene consists in making the actual duration of life approach the potential opportunity. If age-mortality statistics were available from throughout the centuries, it would be possible to ascertain whether the actual span of life has been materially altered for the human race with the progress of time. The records of the past often present themselves in most unexpected ways. The paleontologist and the geologist read the age of the earth from the rocks. An ingenious anthropologist, Professor Todd[3] of Western Reserve University, has attempted to secure a correct appraisal of the ages at death in bygone days by "wringing the secret from the bones themselves left immutable by time in the grave." According to Todd, it is possible by examination of skeletons to estimate the age at death of ancient or primitive populations. For example, from adolescence to the age of 25 years, union of epiphyses is the dominant feature. From 25 to 30 years, closure of sutures continues the tale along with the consolidation of areas, such as the symphysis pubis, which possess rudimentry epiphyses. From 30 to 35 years, the skeleton is at its prime and there is a lull in differentiation. At subsequent ages, other bony structures have distinguishing characteristics.

The study of old skeletal remains in various parts of the world indicates that the "peak" of the mortality curve coincided with a comparatively early age. Todd asserts that the straws of evidence all point in the one direction. The peak of old-age-death, so prominent in modern mortality curves, fades into insignificance the further one recedes from the present day, and in the dimmer records of the distant past there is no real indication of its existence. This does not gainsay the record of an occasional patriarch among men; it is the story of the average man of old. The chief difference, according to Todd, between ancient peoples and civilized populations of today is the apparent fact that the peak of old-age-death is a comparatively modern achievement resulting from greater safety and improved conditions of living. He believes that the difference between the peaks of mortality in primitive and ancient people, on the one hand, and of modern civilized humanity, on the other, is roughly thirty years.

The evident prolongation of human life in the course of time does not apply uniformly to all groups of modern society. Even today one can find the analogue of the older civilizations. In the so-called lower strata the old-age peak characteristic of today is not to be found, owing to the relatively great hazards of life to which these unfortunate people are exposed when not sheltered by specific social legislation. This, at least, is Todd's interpretation of the story in which he has attempted to reconstruct the record of mortality of the life of lost centuries. It inspires a belief that what we call modern civilization has, after all, some positive accomplishment in respect to human longevity among those in whom its influence can make itself most felt.

THE NATURE AND RELIEF OF PARALYTIC ILEUS

Cessation of movements of the bowel may have a train of serious consequences. The problem is always serious to the clinician, particularly because it may incidentally attend operative intervention with other parts of the body as well as outspoken disease. A paralysis of the bowel is a familiar concomitant of violent irritation of the sensory nervous mechanisms. It is frequently one of the undesired accompaniments of the opening of the abdominal cavity as well as traumatization of structures within it. The term ileus has often been applied to such paralytic conditions of the intestines; but as the same expression is also used at times in relation to obstructions of various sorts, it ought probably to be abandoned because of indefiniteness. So-called paralytic ileus may be attended with chemical changes in the blood which have even been charged with etiologic significance for the genesis of the inactivity of the bowel. The clinical importance of ascertaining its nature and possibly a method of averting paralytic ileus is further stressed in recalling that the condition described may become complicated by secondary changes in the wall of the bowel due to stagnation of the intestinal contents, intraperitoneal suppuration or local anemia.[1] The circumstance that it is possible to produce an intestinal paresis experimentally in animals has greatly furthered the investigation of its problems. In man the ileus results occasionally after severe injury to a limb, after a trifling abdominal operation, or even after a severe nervous shock. The laboratory animals seem

to be somewhat less susceptible to the impairment of intestinal motility. Markowitz and Campbell[2] of Toronto have recently confirmed the observations of Wagner[3] that spinal anesthesia promptly restores bowel movements in cases of paralytic ileus. The Canadian investigators believe that the prompt curative effect of spinal anesthesia is due to abolition of an inhibition of bowel movements brought about by laparotomy or other physiologic "insults"; hence probably the paralytic ileus is essentially reflex in nature, and the chemical changes that have been described in the blood are the result and not the cause of the ileus. Markowitz and Campbell conclude that paralytic ileus as encountered in the clinic must be of the nature of reflex inhibition, dependent on the integrity of the reflex arc. Such a conception, they add, implies that the paralysis of the bowel movements observed at laparotomy is a physiologic ileus which, if unrelieved or augmented by other irritant stimuli, merges into paralytic ileus.

THE CHEMICAL NATURE OF CHARCOT'S CRYSTALS

The designation of Charcot's crystals, sometimes also termed Charcot-Leyden or Charcot-Neumann crystals, has been applied to a substance observed in striking crystalline form in certain tissues and their derivatives. They were first recognized in 1853 by Charcot and Robin in the spleen of a patient who had suffered from leukemia. Subsequently Leyden discovered crystals of a similar description in the sputum of asthmatic patients and regarded them as of possible diagnostic value. For the most part the Charcot crystals have either been omitted or continued to represent mere biochemical curiosities in the textbooks of medicine. Böttcher had suggested as early as 1865 that the structures are comparable with the crystals that sometimes bear his name but are usually referred to as spermine crystals. The chemical identity of spermine has now been definitely established and the artificial synthesis of the compound accomplished. In a recent review of this contribution,[4] doubt was cast on the alleged similarity of the Charcot-Leyden crystals and those of spermine phosphate. Apparently, however, the identity has now been made highly probable by German investigators[5] at the University of Greifswald. Thus another item long recognized merely as a name in the literature of the medical sciences has become a well defined chemical entity.

CONFERENCE ON PUBLIC HEALTH

Held in Chicago, March 24-25, 1927

(Continued from page 37)

March 24—Afternoon (Continued)

Public Health Education with Especial Reference to the Use of the Printed Page

Dr. Matthias Nicoll, Commissioner of Health, State Department of Health, Albany, N. Y.: If my remarks seem to apply too closely to my own state of New York, it is not for the reason that I believe New York State to hold a monopoly of knowledge regarding methods of public health education, but because I am more familiar with our own methods than those of others. Our printing bill last year was about $60,000, and if salaries and traveling expenses are included, the total makes up a good share of our budget. There are very few accomplished public health educators in this country or elsewhere, and it is seldom that a state or city possesses an educator who can handle the whole business alone. It is a wise procedure to interest all members of the staff in public health education, encouraging them to present ideas and furnish articles and items of public health interest, from whatever source, for publication in the official bulletin, or for use in addresses or articles on public health. A person furnishing such ideas should be kept track of and encouraged. In other words, understudies and assistants to the director of the division of public health education, if there is one, should be zealously sought for and tried out. In a large department, innumerable items of this kind are consigned to the general files and do not see the light of day until, months or years afterward, they are unearthed and found interesting but too stale to be applicable.

Up to three years ago, the official bulletin of the state department of health was issued as a monthly periodical and had attained quite a respectable age in years. It consisted largely of articles by authorities in various branches of the medical sciences, usually rather technical in character, and not infrequently somewhat too weighty for popular appeal. I fear all too frequently that it was stamped and confined to the library files or ignominiously filed in the scrap basket. About three years ago we began the publication of a weekly bulletin, the *Health News*. From the first it has been a phenomenal success, and the demand for it, not only throughout this country but from many foreign countries, is far greater than the supply. In addition to live news items regarding the health of the state, the bulletin serves as a medium for official orders to the staff, the health officers and the nurses of the state, outside the city of New York. The cost per weekly issue is $145 on a basis of 12,000 copies, and the total annual cost, irrespective of overhead, is $7,540. In this year's budget, the appropriation for the *News* was increased to $11,000, which will enable us to issue 20,000 copies a week. I know of no other state, except California, that is now publishing a weekly bulletin, and that bulletin is made up largely of statistical material. I cannot urge too strongly on those states and large cities which can afford it to publish weekly bulletins of current health events. They serve to keep the health administration "on the map" and to interest a large number of people in what is being done for the benefit of their health and welfare.

While radio talks do not come under the head of the present discussion, I believe that well thought-out topics of current interest in public health, broadcast by radio, at a definite hour each week, are of immense service, especially in the rural districts. Such talks have been given by the state department of health of New York each week to the number of about 257 and, in addition, a mimeographed copy of the "talk" is sent to 147 daily and 472 weekly papers throughout the state. It is found that 70 per cent of the former and 40 per cent of the latter publish these "talks" regularly. This service costs practically nothing and is worth more than the effort to furnish new topics for broadcasting. With the air, as it is at present, so cluttered up with conversation on every conceivable subject, including unsound and even false medical theories and the vawps of charlatans and quacks, antivaccinationists and chiropractors, it is probable that legitimate medical messages will be crowded out or found to be in such bad company that they will be withdrawn, but until that time arrives, it is my opinion that this form of public health education should be continued

I believe that the so-called boiler plate form of public health education has been pretty well abandoned throughout the country It was found by us to be an expensive and unsatisfactory service, especially for the reason that it was impossible to control the time of publication of the series of articles that were sent out in this form It was not popular with the larger newspapers, which preferred to do their own writing, and frequently resented by the smaller ones, which felt that they were being imposed on by giving free advertising space

Close contact with representatives of the daily press is a valuable adjunct in getting out frequent news releases, and for this purpose it is extremely important that some one in a health department should have acquired news sense, and be as familiar as possible with the peculiar psychology of newspaper men, which it is not always easy to grasp How frequently does it happen that a news item which we regard of very little interest is pronounced to be "great stuff" by the brethren of the press, and conversely, what we may regard as a wonderful piece of news and hopefully look for the next day fails to appear There can be no question that the story is frequently lost for the reason that the facts were not presented with due regard for newspaper technic

The division of maternity, infancy and child hygiene, and that of social hygiene have their *own* special methods of publicity The former, shortly after the receipt of a marriage certificate, sends out a pamphlet of instructions to prospective mothers About 30 000 of these go out annually This is a popular service, especially in the rural districts, where the advice of a physician is not readily available and prenatal care by no means all that it should be Baby books are distributed to the 1,300 registrars of the state, and by them sent to each mother on the receipt of a birth certificate These books are technically correct, readable and much in demand The director of the division of social hygiene sends out, four or five times a year, a typewritten pamphlet on venereal disease and subjects relating to sex to a specially selected group, making up about 15,000 persons In the group are included the Y M C A's, Y W C A's school teachers scout organizations, and churches The department also publishes many pamphlets on a great variety of subjects dealing with public health These are sent free on application

Posters are certainly of value in an intensive campaign of short duration and carried on for a definite purpose But posters retained and exhibited for an indefinite time, largely for their artistic value, are to my mind of very limited use Furthermore, I believe that the artistry expended on a poster should never subordinate the definite message that it carries A poster should appeal to the common sense of the public by setting forth, in concise and catchy phrases, advice which it is desired to have followed Pictures of pretty babies and adoring mothers may be useful for decorative purposes but they seldom, I believe, lead to the wide adoption of preventive measures against disease Before closing, I desire to pay my respects to and express my admiration for the editor and author of the best public health publication which comes across my desk, that of the city of Chicago Dr Bundesen's bulletins are always attractive, witty and full of common sense, well printed on good paper and, on the whole models of public health pamphlets

Mr Evart G Routzahn, Russell Sage Foundation New York Not long ago I gathered a few figures as to the circulation of health printed matter At that time I found that in one year more than 10,000,000 pieces of educational printed matter were purchased of the Division of Venereal Diseases of the United States Public Health Service or reprinted by the states, and the cumulative volume of health literature distributed by the Metropolitan Life Insurance Company considerably exceeded 400,000,000 pieces In other instances from one million to six million copies of a leaflet or folder were issued by a national organization Probably the quantity of health printed matter issued by national organizations is equalled by the state and local departments and associations A considerable proportion of what is distributed is not read and another larger section of it, although it is read, does not lead to action

Our educational material, especially that part of it which is printed, can be made much more effective As the means to this end I would suggest 1 More general use of *accepted* principles, technics and forms of skill adapted to our needs I refer especially to the technic of printing principles of psychology, and facility in writing in everyday language 2 Employment of persons to do the work of health education who are trained to do it, and this means that we must first offer training 3 Revision of the methods of supervision and the working conditions under which preparation of health education material is carried on 4 A philosophy and a program for the health education work of official and private agencies Both of these elements are lacking in the work of many agencies 5 Recognition of the time and thought that are necessary in producing publicity material that gets results Comfortable reading demands type of a minimum size of 10 point, unless very short lines are used (from 2 to 2½ inches) an "open" page obtained by space between lines and wide margins, is as important as type size there should be a strong contrast in color between paper and type, lower case letters are easier to read than capitals, shiny paper is not so easy to look at as dull finish paper Well planned, designed and printed text on a good and suitable grade of paper may cost little more than many jobs that look even cheaper than they are

It is sound practice to seek to get the attention of the reader by talking about something that already interests him to begin where he is and lead him from there to what one wants him to become interested in a concrete example gets attention more easily than a generalization, specific words such as toothbrush and carrots, are more quickly understood than broad terms such as care of the teeth and wholesome food, people follow advice most readily when it is made easy for them, and so on Perhaps the most important contribution of the psychologist is in the development of methods of testing the relative attention value of this or that color or form of copy, of finding out in advance what is the strength of a particular appeal and so on Advertising practice can give us a few lessons in the application of psychology to influencing behavior, but in most cases experience in this field must be translated and modified to meet our conditions and limitations One difficulty in applying the experience of commercial advertisers directly to our work is that advertising usually relates to a single concrete object An example of a health education campaign with an objective almost as simple and direct as that of selling tooth paste or yeast is that for vaccination against smallpox or diphtheria

Those who give health instruction frequently do not talk a language that the people most in need of this instruction can understand, and consequently thousands of lives that might be saved are lost annually The person who prepares publicity needs imagination and an understanding of people He also needs to keep up with current facilities and ideas for making printed matter attractive and getting it into use All of this implies the employment of a special worker for the job of health education and publicity At least, it calls for a generous time allowance for a person assigned to the task

To consider the resources most immediately available there is the education and publicity section of the American Public Health Association, which conducts meetings each year of a very practical kind and also has a department of methods in the *American Journal of Public Health* Here are other suggestions Read a book on the subject or two or three of them The Russell Sage Foundation has a reading list on publicity methods Go through the files of the *American Journal of Public Health* for the past three or four years Subscribe to the *News Bulletin* of the Committee on Publicity Methods Especially call in one or more consultants including a good printer and some one who issues good printed matter Seek opportunities for talking over your printed matter informally without reference to a particular printing job. Seek criticism and advice based on what you have already had printed. Invite criticism of your copy from newspaper men and other writers. Ask them to go over it and offer suggestions before it is set up in type. Arrange several dinner or evening conferences with the local group of health workers in which the printed matter of those present shall be discussed—with examples in the hands of all present. Probably at one of these conferences have a good designer of printing present who will criticize each piece in turn, pointing out what he thinks is good practice and what he thinks could be improved. At another time ask a writer to do the same thing with the copy. It may be possible to find an illustrator, a photographer, an engraver to come in for such a discussion.

Organizations that employ educational secretaries pick them up here and there and they learn the work by doing it—some of them very successfully, too. If the worker is to be trained on the job, it seems to me that there are several ways to help him succeed. It is especially important, as has been said, that the publicity secretary should know people and know something of the circumstances under which they will receive the material he is turning out. The publicity worker should be free to leave the office, walk the streets, look at the people or the shop windows, even go to a vaudeville or motion picture show. Study and conference with others in the same work are of special importance to the publicity worker.

Another matter that counts in getting the best work from a publicity assistant is the nature of the supervision given to his work. Better by far that there be some errors of judgment or of skill than that the creative spirit be submerged under the effort to get by. In urging greater freedom for the writer I am assuming that he brings some ability, judgment and experience to the work.

The $1,800 recommended several years ago for a young man or young woman with a variety of training and skill will not draw that type of worker into public health work, because of larger salaries and better opportunities offered elsewhere.

Have we a philosophy? Few seem to be thinking of what persons to reach and how best to reach them, and what they actually wish these persons to do about it. An analysis of the whole problem before printed matter is prepared would sometimes result in a decision not to prepare any, or to prepare something especially for industrial workers or farmers or housewives instead of for the so-called general public.

Through a cooperative effort by some of those here it would be possible to try out a plan of obtaining high grade service in designing folders that can be printed by local printers with the necessary changes required to make the material adaptable to local use. The procedure might be as follows: 1. Appoint a committee, or put it up to the American Public Health Association or National Health Council to appoint one. Let the committee select one or several sizes for a series of leaflets or folders for a particular use. Let them engage a specialist to prepare a layout, including paper, color, type faces and sizes, etc., for an approximate amount of copy, the general outlines of which will be supplied. 2. Another possibility would be to select the basic facts and ideas which should be presented to a particular audience for a particular purpose. Indicate the more important facts and ideas in this material. Check the material for its soundness from the public health point of view. Engage high grade people to write and illustrate the copy. Supply proofs or plates to those who wish to do their own printing. Accept orders for an initial edition.

An average of $5 or less each from the departments and associations represented here would provide several examples of the suggested layout service—type, paper, ink, etc.—with proof copies supplied so that the possibilities could be studied and applied to your own printing by your state or local printers. A test of the copy plan could be made on a similarly modest scale. After plenty of time to study and experiment with these examples there could be discussion of what next to undertake if the idea proved acceptable to a reasonable proportion of those concerned. After further use of the plan a way might be found to provide a revolving fund to finance the project whether or not it was decided that the service should be made self-supporting. This kind of service is so concrete, and its advantages can be illustrated so easily, that it seems probable that departments could secure gifts from interested people to cover their shares in the expense where it would be impossible to use official funds. Is it not possible that the private associations could likewise get special contributions for such services?

Dr. Morris Fishbein, Editor, The Journal of the American Medical Association and *Hygeia*, Chicago: The newspaper is the greatest medium for medical education of the public. Practically all other methods of education reach their largest audiences through the press. Unfortunately, material for publication in the press has to be put in a diction that will be understandable by a person about 14 years of age. The language must be according to the simple old adage "Tell it to Sweeney; the Stuyvesants will understand."

The chief difficulty in securing proper publicity for medicine and for health in American newspapers is the fact that there are as many as five hundred organizations in the health field attempting to secure publicity at the same time, and that individual newspaper editors and newspaper syndicates are also promoting this type of material. Today there is hardly a newspaper of repute in the United States that will take medical advertising matter without checking up its authenticity with the officers of the medical society in the community, or without telegraphing to the headquarters' office of the American Medical Association to find out the real value of the material. Today promoters of nostrums, of cures for cancer, tuberculosis or anemia, or foods or drinks alleged to have special virtues in promoting health secure their victims by a more modern method. The concern hires a publicity counselor and pays him a salary based on the amount of free publicity that he can get for his product in the newspapers. A high priced publicity agent who can get the product on the first page a certain number of times a week will do much more for his concern than could be accomplished by the purchase of advertising space.

The public is interested primarily in things that can be dramatized for them, and the greatest element of drama is conflict. Such battles fought in the public forum as the Rhinelander affair, the Snyder trial and the Hall-Mills case attract millions of readers. Medicine, too, has its tremendous conflicts, and when they are sufficiently dramatized they accomplish much for health education and the benefit of the public. The health educator who knows how to take advantage of such a news feature for the education of the public, and who is able to recognize the drama inherent in such an event, will accomplish much for the benefit of his readers.

Much of the health education conveyed to the public today is given by means of the newspaper health column. The first of these has been before the public less than a score of years. Today about fifteen such columns are syndicated through many newspapers. Some of them represent the highest type of medical education. They are cautious in their announcement of new discoveries and in the status of new medical work. Sometimes these columnists promote individual notions without giving their public a clear understanding that these are notions and not established medical facts. A few of these columns, however, are vicious in the promulgation of "patent medicine" advertising or preposterous health advice.

It is difficult for the public to distinguish between newspaper material promoted with altruism and that issued primarily for personal gain. Never a week goes by without a telegram from newspapers and from press associations all over the United States coming to the headquarters office of the American Medical Association, and asking for immediate advice on medical news. The headquarters office is able to provide replies because study has been made of the way in which the newspapers work. The newspaperman's chief diet is news—news is material that must be published immediately. Through the various departments of the Association, information concerning any new discovery in medical science or in the field of quackery is promptly available. In the Bureau of Investigation is a file of more than 125,000 cards cross-indexing every type of quackery and every person who has been engaged in quackery in the United States for many years. In its biographic department is the record of every physician in the United States from the moment he enters medical college until he dies, and the card is left for twenty years after that In association with this is a biographic file in which are kept newspaper clippings concerning physicians that have come into the headquarters office through the clipping bureaus covering every portion of the United States Finally, the American Medical Association prepares and publishes a periodical known as the *Quarterly Cumulative Index Medicus*, in which appears reference to every article appearing in any scientific publication, indexed by the subject and by the author's name When a telegram is received from any newspaper regarding any medical discovery, it is possible to locate immediately the scientific article on which the announcement may be based, reference to all the previous work of the investigator, and a statement as to his position in medical school research institution or other organization Such information is invaluable in determining the authenticity of any medical item Moreover, connections have been established in all the great medical centers of the world so that information can be had immediately by telegram or by long distance telephone, when it is required promptly for an important purpose

Such syndicate services as the Associated Press, the Newspaper Enterprise Association, and Science Service constantly check medical news material through the American Medical Association in order to be assured of its authenticity

More and more newspapers are asking for medical help in the preparation of considerations of special topics Such a series as that appearing in the New York *Herald Tribune*, covering the craze for reduction in weight, is a response to this request But not all newspapers are equally careful in the checking of scientific material Recently, in the Sunday issue of one of the Chicago newspapers appeared an announcement that a physician had been arrested under a warrant that accused him of unethical conduct and of malpractice In the same issue was a feature article as to the remarkable results secured by this physician in reducing the weight of some aged actress by the wholesale removal of fat from those portions of her anatomy where it was most abundant The *feature article was an advertisement, but it was not labeled,* according to the government regulations, with the significant letters 'adv" at the end It appeared, instead, as a portion of the magazine section of the paper It is well known that such magazine sections may be printed some time in advance of the news sections, but the questionable character of the publicity for the physician concerned was not in any sense of the word a new question

It is well known that feature articles are manufactured to fit special occasions, and their development frequently represents the work of weeks or of months In many instances, such feature articles are written by men noted for their contributions to medical education of the public The medical writer who respects the ethics of his profession will not build a feature article merely for the opportunity of selling it, but will limit himself to such matters as constitute actual education It is a simple matter to exploit the half baked discovery of some enthusiastic medical investigator as an achievement It is a far more difficult matter to prepare in a form that is interesting and instructive to any lay reader the scientific developments that are on a thorough basis and that constitute established medical knowledge

The medical profession today is attempting to form some organized method for supplying newspapers with material and yet preventing injustice through the overadvertisement of individual physicians, and through the furnishing of details concerning the personal lives of patients which the public should not have The medical education of the public is the one certain method of overcoming the evils of quackery of cultism, and of medical fraud

President Phillips I feel that I should state the reason why I am obliged to withdraw at this time Just before I left New York news came to me of the death of a very dear brother, and I can only reach his home to attend his funeral by leaving at this time

Dr E B Heckel, chairman of the Board of Trustees of the American Medical Association, took the Chair

DISCUSSION ON PAPERS OF DR NICOLL, MR ROUTZAHN AND DR FISHBEIN

Mrs W B Maloney, Editor, New York *Herald Tribune* Magazine, New York For a great many years I have believed that the people who knew committed a cardinal sin by not giving their knowledge to the world I believe that knowledge is without influence until it is given to the public It is without power until the public accepts it You can only make the public accept it by using all the agencies which reach the people, and chief among these is the daily press Seven million dollars worth of newspaper is used every Sunday in the United States, and I do not believe the public health work receives its full share of that $7,000,000 It is necessary to teach the scientific man and the highly professional groups how to reach the public The editor is not entirely to blame In my time, which has been a long time, I have seen newspapers break down their prejudices against health news I have seen a cancer item printed on the first page of a newspaper Ten years ago you couldn't get any newspaper to publish the fact that anybody in the world had died of cancer The rule of most newspapers was never to use the word it is still a rule *in some offices never to use it on the first page*, *it is also the* rule with some monthly magazines That has been largely overcome Something has been said today about preventive medicine without cost, curative medicine at cost I happen to have had to work my way through college because my father was a doctor who didn't collect his bills I think most doctors have large non paying practice I have known Dr Wood to work all night long on somebody who didn't have a dollar in the world I have known Dr Brooks to forego a $500 consultation fee in order to attend a man who didn't have a penny to pay him I think that if there is any purpose in this meeting at all, it is to wipe out all those little prejudices those little feelings that give us patent leather hides There is too much work to be done, nobody has any time to be personal Editors are sometimes wrong and they can stand being corrected, doctors are wrong sometimes and they must be willing to be told so That also applies to public health workers and social workers Recently, with the aid of the American Medical Association I put through a campaign to educate the public on "girth" control I did that because it was possible by putting out the article to get 20 000 letters from women who wanted to know if they could live on lamb chops and grapefruit There were no means of proper scientific control and education until the newspapers were used by the people who had the accurate information to give It has been a very difficult thing to make some of the professional people believe that it is a legitimate thing to do It is not only legitimate but an obligation if you really believe in preventive medicine or curative medicine

Dr James A Tobey, New York The suggestion made by Mr Routzahn for a committee to attempt to set specifications and standards seems to me well meriting a serious follow up Five years or so ago the *American Journal of Public Health* carried a significant editorial entitled "Pamphleteering and Public Health ' in which an endeavor was made to show there were somewhat too many pamphlets in this field The United States government alone has between 1,200 and 1 500 separate and distinct pamphlets on public health subjects If you want to know about milk you can get literature on this topic from the United States Public Health Service the Department of Agriculture the United States Children's Bureau or the United States Bureau of Education and you can obtain many different pamphlets on that subject and this fact is also true of other subjects When you go outside of the national government and approach the voluntary agencies or the states and the cities it almost staggers comprehension to learn how many pamphlets there are I strongly advocate that this unduly copious supply be reduced and standardized As Dr Fishbein has well said more attention should be given to newspaper publicity which after all is by far the best type in public health work

Dr Herman N Bundesen Health Commissioner, Chicago I feel that probably one of the greatest single successes of the Chicago department of health has been the issuance of health literature in a way really to reach the people Dr Nicoll wanted to know how much we spent last year for publicity in the department of health of Chicago *The bill for bulletins a* publications alone was $146,000. Several speakers here have said that their health department appropriations are only $10,000 or $12,000. I might say that the appropriation for the health literature last year in Chicago was $6,250. We had to raise the $140,000 outside the health department. All our large publications have passed through the hands of Dr. Fishbein of the American Medical Association, and have been censored as to their accuracy. The matter of raising the money by subscription isn't a hard job when one gets the confidence of the people. We got out the baby book, of which there have now been issued a little over 5,000,000 copies in eighteen months. We also got out a booklet on prenatal care. This publication has been able to reach more than 100,000 mothers in the city. We try to distribute the book to every pregnant woman. It is a seventy-two page booklet on the subject "Before the Baby Comes." To print that booklet cost something like $17,500 for the first 100,000 copies. Samuel Insull is a great public utility advertising genius. Insull, William Wrigley, John R. Thompson, John Hertz, the Yellow Taxi man, and people of that kind are the ones who have financed all our publications. We are absolutely convinced it pays to advertise, no matter what commodity is advertised. Why did they sell so much Peruna? Because there was any value to it? Why did they sell so many Lydia Pinkham's pink pills? Why do they sell millions of dollars worth of the food Postum Cereal? Who doesn't want red cheeks? Who doesn't want sparkling eyes? How are they going to get information about these things? From the breakfast food manufacturers until health officers use better tactics to put over health information in the same way,—the way the public needs it. People are interested in just that kind of publicity. It may not work in other places, but it was worked in the city of Chicago. From a publicity point of view we have been able to sell health to the people not only in booklets, but also through the newspapers. The newspapers have been very kind to the Chicago department of health.

The point I am driving at is that you can sell public health. I have been asked what I thought made the bulletin of the health department popular. Who writes it? I write that bulletin myself, and not one issue ever goes out that isn't read to Laura Belle, one of my six youngsters. When she gets something she doesn't understand, we try to rephrase it in language she can understand. This puts it over with the great mass of people. Maybe people do not lack intelligence, but who wants to come home, tired out, and read a lot of small type? Nobody likes to do that. Public health can be sold just as anything else can be sold. The methods are those of the men who are writing advertisements, who are being paid fabulous sums to write ads that put things over. If any of you are not getting the bulletin of the Chicago Department of Health we will be glad to send it to you. If you will look over the illustrations you will see that every one of them, or at least the vast majority, are based on some ads; that is, the ideas are based on ads. I think that you also can sell public health. But it must be sold in a simple way. I think that some of the finest literature in respect to simplicity is the magazine *Hygeia*. If we could get *Hygeia* into every home in Chicago we wouldn't have to worry about cancer fakes or various quackeries. The thing that we must do is to give the people the material in a way so that they will take it, and the way to do that for the general public at large is by simple language, well illustrated. Ask the people who are editing the bulletins whether they are editing it for the doctors or the lay people. Build up the bulletin to the group that you are trying to reach. We in Chicago are trying to build up our bulletin to educate the people of the city. I might say there is hardly a week, hardly a Monday morning, when our bulletin is released that all the five newspapers don't carry from a quarter of a column to a whole column of health matter. When you can get a circulation of millions then you can do something.

March 25

Chairman Heckel: One paper which should have been presented yesterday we will be glad to listen to now.

Relation of Voluntary Health Agency to Physicians and Health Departments

Dr. Linsly R. Williams, New York.

This paper is published in full in this issue of The Journal.

DISCUSSION

Dr. George M. Fisher, President, Medical Society of the State of New York, Utica, N. Y.: I am going to offer a resolution:

Whereas, It is the common idea of all physicians that the health organizations and physicians should work together; therefore be it

Resolved, That the American Medical Association be requested (we can't say what they will do because they are an independent organization) to appoint a committee to work in conjunction with said committee from lay organizations and report at one of their annual sessions, probably next year.

I make that motion and resolution.

Dr. Olin West, Secretary and General Manager of the American Medical Association, Chicago: When invitations were forwarded to those who are participating in this conference, the statement was positively and definitely made that there would be no voting on any sort of a proposition.

Chairman Heckel: The Chair would like to state that the Board of Trustees of the American Medical Association has a standing committee that is always ready to consider any proposition by any organization to the American Medical Association. The standing committee first considers the proposition, whatever it may be, and then it is referred to the Board of Trustees, which takes the final action.

Dr. George Fisher: I would request that that resolution be referred to the Board of Trustees. Is that right, Dr. West?

Secretary West: I think the Board of Trustees will be very glad to consider it, Dr. Fisher.

The motion was seconded, put to a vote and carried.

Dr. W. S. Leathers, Professor of Preventive Medicine, Vanderbilt University School of Medicine, Nashville, Tenn.: I believe that mistakes are being made by certain voluntary agencies, and this is largely due to the fact that the principles which Dr. Williams enunciates are not being observed. Much improvement has occurred in recent years in effecting a better understanding between official and voluntary agencies and the medical profession, but there is still need for continued consideration of this matter. It is my purpose to relate an experience which seems to me better to illustrate what I mean than by discussing in an abstract way the problems involved. In the state from which I come, a fight is on for the establishment of a sanatorium for the care and treatment of tuberculous persons. About two years ago the legislature passed a law requesting the governor to appoint a commission to study the control of tuberculosis in Tennessee and make recommendations with reference to it to the legislature two years hence. This commission is composed of eleven persons. The state health officer is chairman. It is felt by the commission at this time that it would be a mistake to appropriate money for a sanatorium. The secretary of the Tennessee Tuberculosis Association prepared a bill which was introduced into the legislature asking that about one-half million dollars be appropriated for the building of three sanatoriums in the respective subdivisions of the state. This bill was drafted without the knowledge of the state health commissioner and introduced into the legislature without conference with him. Obviously, this procedure was calculated to weaken the administrative position of the state health officer in projecting a program which in his judgment is wise and proper. A representative of the National Tuberculosis Association has been active in promoting the campaign for the establishment of a state sanatorium. In view of the fact that the commission for tuberculosis control, of which the commissioner of health is chairman, does not favor at this time sanatorium development, this has the effect of opposing the program of the state department of health. While it may not be the intention of most of those interested in the sanatorium to weaken the administrative position of the state health commission, it will without question have that effect in the event that the advocates of the sanatorium are successful. When it is maintained before the citizens of a state that the plan or policy of a state health department is not sound, especially when it concerns a big problem, as providing institutional care for the tuberculous, it can only result detrimentally to the interests of the official health agency. It appears to me that an agency which pursues a course that is antagonistic to the policy of the state health department, in view of the circumstances related, is following an unsound procedure It is not good from the standpoint of public health administration or from the standpoint of the medical profession I may say that the State Medical Association of Tennessee, through its secretary, supported the program advocated by the tuberculosis commission, and a large percentage of the physicians of Tennessee are behind and in accord with the policy I believe that a voluntary agency which has its headquarters in a distant city and is honestly endeavoring to relate its work to local conditions should invariably assume a judicious and constructive attitude with reference to the state or local department of health It is true that a state tuberculosis association is somewhat autonomous, but the situation has been aggravated by advice and activity at headquarters The man on the ground can usually handle problems of this kind fairly well if given an opportunity, and any advice or direction that tends to bring about disagreement and discord locally is most unfortunate

Dr Samuel W Welch, Chairman, Alabama State Board of Censors and State Health Officer, Montgomery, Ala I want to endorse everything that Dr Leathers has said The paper which has just been read is sound in theory and in pronouncement The difficulty is that that line of procedure which has been outlined in the paper is not followed in the rural states It is not a sound policy for any volunteer agency to formulate a policy outside the state without knowing the conditions that exist in the rural district and undertaking to apply methods applicable to urban life to the rural district without regard to the opinions, the knowledge of the man on the ground in the rural district We are students of conditions as they are, and after we have worked out our programs, volunteer organizations ought to come in and strengthen our hands and help us develop those programs and help us to grow with our people, make us strong with our own folks Any agency that interferes with the leadership of the board of health in the state is bad, it is rotten, it is doing a great deal more harm than it is doing good A voluntary agency ought to realize that its highest obligation is to build permanently a governmental agency and subordinate itself to the leadership of that governmental agency It is making a serious mistake in the rural districts of this country. I am not discussing urban conditions I am talking about the rural South and the the rural West

Mr Homer Folks, State Charities Association, New York In New York State since 1914, when Dr Biggs became commissioner, the state health commission has always been the most active and dependable member of the executive committee of the voluntary agency In all these years we have never appeared in Albany on opposing sides of a question we have always been together The general principle and the practice in New York, which I can speak for is exactly 100 per cent in line with Dr Welch and Dr Leathers' suggestions

Secretary West I practiced medicine at one time for about twelve years, and for another twelve years I was engaged in public health work, all in the state of Tennessee I was health officer of that state for some time Tennessee is in reality three states The topographical conditions and many others make it impossible, even if the necessary money were available, to establish and maintain a hospital large enough to make it worth while to undertake to do it There are many other factors in the situation with which no man outside the state could be familiar The state health department does know the situation In the meantime, four fairly efficient county hospitals for the treatment of tuberculosis have been developed in Tennessee Based on my experience in the state, it is my opinion that the solution of the tuberculosis question will be found in the right kind of field work, the maintenance of proper educational work, and in the establishment, when feasible, of county or district hospitals I believe that the state board of health's position in this matter is right I believe for a volunteer agency even though it maintains representation in the state, to undertake to foster another program than that which has been decided on by the official agency, with the advice and counsel of a commission composed of some of the best citizens of the state is bound to be harmful I believe that with respect to public health work the whole thing is an educational process We are dealing with problems beset with difficulties that are established by the inherent, inherited and fundamental ignorance, superstition and lack of knowledge on the part of the people, even the best of them There has been too much hurry, too much hurrah, and *sometimes too much stuff* has been put on paper that couldn't be demonstrated as being accomplished fact Another conviction I have is that any demonstration or any sort of an activity undertaken by a health department official, volunteer or anything else, that destroys the confidence of the public in its official agencies, if those official agencies are honestly striving to do their duty, have a definite program outlined and are working at it, does more harm than good I believe that any demonstration that goes into a community no matter who puts it on, that destroys the confidence of the community in its own medical profession does more harm than good I believe that a demonstration in a community that costs much more money than that community is able to provide, or that the community cannot take hold of and carry out after the demonstration is gone, and those that have the money are gone, does more harm than good No public health movement of any kind is going to succeed, finally and definitely, that does *not take the medical profession into* the confidence of its promoters and does not make the medical *profession an element of first consideration If the* profession is slow to take hold, if the profession is incompetent, then the job to be done is to build up the right sort of sentiment in the medical profession and among the public It can be done My judgment is that the medical profession as a whole is *just as much interested in promoting* public health as any body, just as willing to carry its end of the load and a little bit more than anybody else is willing to do But they are not willing to take hold of a thing and run away with it nor to be taken hold of and run away with If it takes longer to do the job, take longer to do it, and get more permanent results

Dr Linsly R Williams, National Tuberculosis Association, New York It is quite clear that the health department and the health officer should take the leadership in all types of health work A certain *number of health officers of states* come to me and say, 'Why don't you fire your agent out there?' Our state associations are entirely autonomous, they are self perpetuating bodies with boards of directors elected by membership and their boards of directors choose the executive officer I have nothing to do with his selection It is true that it is possible to bring a great deal of pressure *to bear to see that a secretary is removed* but *only* under grave situations These relationships almost always get down to the personality of two individuals I haven t been able to solve certain differences I have urged a number of secretaries to resign but they have told me they were going to fight it out I can t fire them The voluntary agency should aid in promoting the activities of the state health departments I am wholly *in* accord *in the question of always being sub*ordinate to the health official I believe that they would be subordinate if the health officer always took the leadership if the health officer were always an important member of the executive committee of the voluntary agency *If* a little more effort is made by health officials to secure the support of the voluntary agency, we can go a bit further *But* any group of individuals has the right to criticize a *governmental* authority I think I have sensed in one or two health officials a feeling that they are above criticism or suggestion On the other hand, we get a great deal more progress by sitting down at the same table and talking things over Let s have more frequent conferences Let us agree so far as we can let us compromise, and try to push on the work together The question *has been raised that we should not go forward* with health activities unless we know that we can receive the financial support from them A great many of us have been seeking in vain to find out how much a given community can afford to pay for health work Some of the counties have recently put forward a little slogan for their health campaign, "Give us a mile of road" when they were putting in several *hundred miles in the* country They can afford the hundred miles of road but they can't afford a decent little health department for a county I should like to know what the formula is as to how much the people can pay

(To be continued)

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals, education, public health, etc)

ALABAMA

Bills Introduced.—Senate bill No 170 would authorize and regulate the practice of chiropractic, and provide for establishing a board of chiropractic examiners Senate bill No. 256 and house bill No 467 repeal the sections of the code relative to the reports of births and deaths by physicians and midwives House bill No 395 would repeal the workmen's compensation act

CALIFORNIA

Placement Bureau.—The placement bureau maintained in the office of the secretary of the California Medical Association, San Francisco, during 1926, successfully placed thirty-five physicians and ten nurses and stenographers.

Changes in Health Officers.—Dr Frank G Crandall has been appointed health officer of Santa Barbara County; Dr Benjamin F. Saylor has succeeded Dr Earnest Dozier as health officer of Shasta County, and Dr Richard Stewart Hiatt has been appointed city health officer of Ceres.

University News.—Thirty-seven graduates in medicine enrolled for the summer course in the University of California Medical School, San Francisco, which opened, June 6, and closed, July 2, twenty-one were from California, four from Idaho, three each from Washington and Oregon, two each from Utah and Arizona, and one each from New Mexico and Nevada——The National Research Council, New York, has awarded a grant of $15,880 to the University of California to support investigations being made by Dr Herbert M Evans, chairman, department of anatomy, with particular reference to the relation of nutrition to fertility and the relation of the endocrine glands.

Society News.—Dr. Harry Spiro, San Francisco, addressed the San Joaquin County Medical Society, June 2, on "Heart Disease"——Dr John V Barrow, Los Angeles, addressed the San Diego County Medical Society, June 14, on "Morbid Changes in Amebeans"——The San Bernardino County Medical Society conducted a symposium on common infections of the upper respiratory tract, May 3, the speakers were Drs. Lenore D Campbell, Gayle G Moseley, Charles A. Wylie William W Savage, Carlos G Hilliard and Kenneth L Dole. ——The Los Angeles Orthopedic Club was host to members of the American Orthopedic Association during the annual meeting in Yosemite Valley, June 13-17, housing the entire party at the Huntington Hotel as their guests; there was a dry clinic, Friday afternoon, June 10, a banquet, Friday evening, a trip to Hollywood, Saturday morning, and a luncheon, Saturday evening before the party left for Camp Curry. The party went to San Francisco the following Friday night, where a dinner was held at the new home of the San Francisco County Medical Society, following a dry clinic, Saturday, there was a sightseeing trip, a dinner in Chinatown and a theater party The party disbanded, June 19.

CONNECTICUT

Diploma Mill Echoes—Slabotsky, McCubbin and Munch.—Further testimony at the rehearing, in New Haven, of the eleven eclectics whose licenses were revoked as a result of the diploma mill investigation indicated that Dr. Samuel M. McCubbin, formerly secretary-treasurer of the Eclectic Medical University, Kansas City, had issued seven or eight degrees at $10 each to Dr George Munch, then secretary of the Florida Eclectic Examining Board and now serving in the penitentiary for using the mails to defraud in connection with illegal medical diplomas McCubbin testified, it is reported, that some of these degrees were honorary while others were not so labeled, and that neither Munch nor those who finally received the degrees ever attended the Eclectic Medical University of Kansas City. Some of the "graduates" of this school later went to Florida to take the state examination before the eclectic board Dr. Samuel Slabotsky is reported to have testified that he had attended the Eclectic Medical University three years previous to the World War and, on receiving his discharge in 1919 from the army, went to the Kansas City College of Medicine and Surgery after learning that the Eclectic Medical University had closed; before leaving for an embarkation camp in 1917, he received two diplomas from the Eclectic Medical University and these were introduced in evidence at the rehearing. Nothing was brought out in the testimony at this time as to why there should have been two diplomas.

GEORGIA

Personal.—Dr. Stewart R. Roberts has been appointed in charge of the free heart clinic for white patients who are unable to pay at Wesley Memorial Hospital, Atlanta, under the auspices of Emory University School of Medicine.——Dr. Frank K. Boland has been elected president of the University of Georgia Alumni Society.——Dr. Robert F. Wheat, Bainbridge, has been appointed a member of the state board of medical examiners.

Summer Clinics.—Emory University School of Medicine, Atlanta, will offer again, from July 9 to July 23, a series of summer clinics daily except Saturday and Sunday. Work will be in the form of a presentation of cases and of talks on recent aids to diagnosis and the newer forms of treatment in internal medicine, general medicine, gynecology, pediatrics, obstetrics, orthopedics, genito-urinary diseases and diseases of the eye, ear, nose and throat. Clinics will be held at the Wesley Memorial Hospital and the Emory University Division of Grady Hospital on alternate days.

Society News.—Dr. Theodore Toepel, Atlanta, addressed the Fulton County Medical Society, June 2, on "Nutrition and Growth in School Children" and Drs. James E. Paullin, Jr, "Bowcock and Wood" on "Hypertension and Its Complications."——Dr. Joseph Yampolsky, Atlanta, has been elected president of the Georgia Pediatric Society, and Dr. William N Adkins, Atlanta, secretary.——Dr. Charles J. Jenkins, Edison, was elected president of the second District Medical Society, May 8——Dr. Frank K. Boland read a paper before the Fulton County Medical Society, Atlanta, June 16, on "Abscess of the Lung"; Dr. Carl C. Aven gave a clinical talk on "Physical Signs in Heart Disease."——Dr. McIntosh M. Burns has been elected a member of the board of education of the city of Atlanta.

ILLINOIS

Fiftieth Anniversary of State Department.—The Illinois State Health Department was organized fifty years ago, July 1. During that period, the life expectancy of the average child born in the state has increased at least fourteen years, according to the editor of *Illinois Health News*, and the expenditures for public health work in Illinois have increased from about $10,000 to $500,000 a year. Another great change in the half century has been the increase in heart disease, which now is ahead of tuberculosis in the mortality column, whereas fifty years ago it was fourth or fifth.

Personal.—Dr. Clarence T. Roome is moving to Santa Barbara, Calif., it is reported, to engage in the practice of medicine; Dr. Roome was health commissioner of Evanston for about fifteen years——Dr. Harry Olin, St. Louis, has been appointed radiologist to St. Elizabeth's Hospital, Danville, to succeed the late Dr. William H. Miner.——Dr. Walter C. Martini has resigned as medical director and superintendent of the Outlook Tuberculosis Sanatorium, Champaign, and will engage in work at Springfield——Dr. and Mrs John S. Allen, Keithsburg, celebrated their golden wedding anniversary, June 21.——Dr. Fred M. F. Meixner, Peoria, has been appointed an examiner of aviators by the U. S. Department of Commerce.

Chicago

Hospital News.—An oil painting of the late Dr. William E. Schroeder, chief of staff of Wesley Memorial Hospital, was unveiled at memorial services at Wesley Hospital in June.

Personal.—Dr. James G. Carr was elected president for the ensuing year of the Alumni Association of Northwestern University Medical School, and Dr. George K. Fenn secretary-treasurer.——Dr. Dallas B. Phemister was elected president for the ensuing year of the Alumni Association of Rush Medical College of the University of Chicago, and Dr. Charles A. Parker, secretary.——Dr. Frank L. Rector gave an address at the fifty-second annual meeting of the Alumni Association of the University of Buffalo, June 8, on "Relation of Industrial Medicine to the Private Practitioner."

Hospital Reorganized.—The president of the board of directors of the Washington Park Hospital writes that the staff and the board of directors of that institution have undergone reorganization, and that the name will be changed to the Washington Park Community Hospital as soon as the necessary legal steps can be effected. Among the directors now are Prof. Anton J. Carlson, Ph.D., University of Chicago, and Dr. Arthur C. Kleutgen; the other members of the board of directors are business men. Dr. Francis P. Hammond has been made president of the staff and chief of the surgical division, and Dr. Roy R. Jamieson, chairman of the medical section of the staff.

University News.—The total attendance at Rush Medical College (University of Chicago) for the spring quarter was 260, exclusive of those registered for medical instruction in the south side departments——Subscriptions from 101 contributors for the clinic of internal medicine named in honor of Dr. Frank Billings in the new hospital building on the Midway totaled nearly a quarter of a million dollars, the president of the university announced at the June convocation. An anonymous donor has placed in the hands of President Max Mason the sum of $15,000 for gifts or loans to members of the University of Chicago, active or retired, in times of peculiar need. The University of Chicago has the assurance of funds for an endowment of the departments of obstetrics and gynecology in the new Chicago Lying-in Hospital to be erected at the university; actual operations on this program of development, President Mason said, will be under way by January, 1929.

Dr. Crane Expelled.—The *Bulletin of the Chicago Medical Society*, June 18, reports that Dr. Milo A. Crane of Elmhurst, charged with unethical conduct, has been expelled from membership Dr. Crane has for some time been advertising in *Physical Culture* an alleged course in "drugless healing" on the correspondence plan, granting "special diplomas" on the completion of the "course." The advertisements appeared under the trade name, "Crane Sanitarium, Department of Schools, Elmhurst, Ill." The Crane Sanitarium was also advertised in *Physical Culture* as being "operated by Drs. Crane and Burkhardt, specialists in obstinate and chronic diseases" Presumably as a drawing card, the advertisement adds that one of these men (it is not clear which) was for "many years house and examining physician for Bernarr Macfadden." According to our records, Milo A Crane was born in 1874, received his medical diploma in 1907 from the Detroit College of Medicine and Surgery, and was licensed in Michigan the same year, and in Illinois two years later.

INDIANA

Personal.—Dr. Sylvester I Arthur, Princeton, has been appointed health officer to succeed the late Dr Robert A Cushman——Dr. James Frank Dinnen, Fort Wayne, has been appointed chief surgeon of the Erie Railroad System with headquarters at Cleveland; Dr. Dinnen, for the last ten years, has been assistant chief surgeon of the Nickel Plate Railroad.——Dr. Weir M. Miley, Anderson, has been appointed a member of the board of trustees of the city schools——Dr. and Mrs. Boston H. B. Grayston, Huntington, celebrated their golden wedding anniversary, June 19——Dr. Charles H. Keever, Indianapolis, has been appointed coroner of Marion County to succeed Dr. Paul F. Robinson, who was killed in an automobile accident a few days ago

Another Diploma Mill Exposed.—Following an exposé of the "College of Drugless Physicians" of Indianapolis, by the Indianapolis *News*, Otis J Briggs, dean of the school, was arrested, June 25, on a charge of conspiracy to commit a felony in connection with the issuance of fraudulent diplomas Briggs eventually confessed that he had issued twenty-one fraudulent diplomas for doctors of naturopathy He filed sixteen applications for licenses recently with the state board of medical registration and examination, presenting to the board some diplomas which were dated back so the applicants could be licensed without examination. An amendment to the state medical practice act requires all persons entering practice after Jan 1, 1927, to pass an examination before being licensed According to Briggs' confession, the following persons were granted diplomas by the College of Drugless Physicians, March 29, 1927, which diplomas were dated back to Dec 15, 1926

Hiram C. Hoskins, 1912 Highland Place, Indianapolis
H. Smith Dulin, 603 North Senate Avenue, Indianapolis
Francis G Cox, 1912 Highland Place, Indianapolis
Robert O. Pettiford, 603 North Senate Avenue, Indianapolis
Otto Adams, 603 North Senate Avenue, Indianapolis
Charles R Parker, 710 North West Street, Indianapolis
May Dulin, 603 North Senate Avenue, Indianapolis
Marie Fleece Morris, Anderson, Ind

Others to whom Briggs granted diplomas that were dated back were Wilby Gwynn, John Hill, Greenfield, Ind , Fritz Laderhaus; Henrietta Sing, and a man named Chapman from Huntington, Ind Briggs' undoing came when a reporter for the Indianapolis *News* applied for enrolment in the "College of Drugless Physicians," June 18 In a few hours, the reporter, Walter A Shead under the name of Alfred Alonzo Shedd, emerged from Briggs' office with a degree of doctor of naturopathy dated back to Nov. 23, 1926, for which he paid about $110, although he had no medical training whatever. The activities of the College of Drugless Physicians of Indianapolis will be laid before the grand jury which convened, July 5, and a complete investigation of its ramifications probably will be made. Briggs is a chiropractor, it appears, with degrees from various drugless schools He is the founder and president of the American Drugless Association and from time to time, has been connected with the Central Scientific College, the New Era Physio-Medical College, the American Occult College and the Indiana Chiropractic College.

IOWA

Anesthetists Resign.—Four members of the staff of anesthetists of the State University of Iowa College of Medicine, Iowa City, resigned, July 1, it is reported. Those who resigned were Drs. Louis W. Harding, Elam E. Lashbrook, Mary Ross and Forrest P. Cartwright

Personal.—Dr Charles Palen has been appointed president of the staff of Mercy Hospital, Dubuque——Dr. Grant J. Ross, Sioux City, celebrated his eighty-fifth birthday, recently.——Dr Arthur L Bryan has been reelected health officer of Muscatine——Dr Henry C Young, Bloomfield, was elected president of the Des Moines Valley Medical Association at the fifty-fourth annual meeting in Ottumwa, June 21

Society News.—The Austin Flint-Cedar Valley Medical Society will meet, July 12-13, at Cedar Falls——Dr Eleanor M Hutchinson resigned as president of the Calhoun County Medical Society following her acceptance of a position at the new federal reformatory for women, Washington, D C——The Upper Des Moines Medical Society was the guest of the Palo Alto County Medical Society, recently, at Emmetsburg; clinics were held at the Park Hospital Clinic by several physicians from Mason City Seventeen patients were present, the histories, and physical and laboratory data having been previously prepared by members of the Palo Alto County Medical Society During the evening, the ladies attended the theater

KANSAS

Bill Introduced.—House bill No. 738 defines homeopathy, establishes qualifications of homeopaths, and provides for examinations of applicants and the issuance of certificates.

Hospital News.—Dr Jabez N. Jackson, Kansas City, President of the American Medical Association, gave the address at the dedication of the new building of Christ's Hospital, Topeka, May 30——The Southwest Protestant Hospital Association is constructing a $50,000 hospital at Dodge City, which, when completed, in about eight months, will be turned over to the Christian Church.

Personal.—Dr Joseph E Hawley will celebrate the completion of fifty years in the practice of medicine in Burr Oak, July 11, an invitation is extended to the public, especially the old settlers and the physicians; there will be music by the Burr Oak Band, singing and speeches——Dr Frank M. Wiley celebrated the completion of fifty years in the practice of medicine in Fredonia, June 17 The celebration was attended by almost every member of the Wilson County Medical Society.

University News.—The recent legislature appropriated $300,000 for the erection of new buildings for the University of Kansas School of Medicine, Kansas City, $200,000 being for an additional ward unit, and $100,000 for a new nurses' home A research fellowship for the study of hypertension under the supervision of Dr Ralph H Major was recently given to the school of medicine by Eli Lilly and Company, Indianapolis; the fellowship amounts to $1,800 a year, and Mrs Vera Johnsmeyer Jones has been appointed fellow.

Society News.—Dr. Damon O. Walthall, instructor of pediatrics, University of Kansas School of Medicine, gave a demonstration before the Jackson County Medical Society, recently, on "Scrotal Tumor in the New-Born," and Dr. Joseph B Cowherd on "Enlarged Thymus in the New-Born."——Dr Richard L Sutton, professor of dermatology, University of Kansas School of Medicine, held a clinic for the Pettis County Medical Society, Sedalia, April 21.——Dr Clinton C. Fuller, Norton, has been appointed head of the full-time health department for Cherokee County, effective, July 1.

KENTUCKY

Personal—Dr Judd E Hammond, Lexington, has been appointed medical examiner for the aeronautics branch of the U S Department of Commerce——Dr John C Morrison, Hickman, has been appointed health officer of Paducah, effective, August 1, to succeed Dr Francis M Munson, who resigned several months ago

Graves County Barbecue.—The Graves County Medical Society and the auxiliary held a barbecue at Sedalia, June 16 following which there was a scientific program, comprising addresses by Dr John H Shelton, Mayfield, on "Puerperal Eclampsia', Dr Frank Boyd, Paducah, on 'Fractures,' and Drs Edwin A Stevens, Harland V Usher and John F. Kirksey

Statue of Ephraim McDowell—The state of Kentucky has selected Dr Ephraim McDowell as one of the two representatives of the state whose statues are to be placed in the National Hall of Statuary in the Capitol Building, Washington, D C Dr McDowell died in 1830 his grave in Danville is marked with a beautiful shaft provided by the Kentucky State Medical Association The other statue to be placed in the National Capitol will be that of Henry Clay The statues will be donated to the state by Mr Isaac W. Bernheim of Cincinnati

MARYLAND

Gift for Children's Ward.—Mrs Henry Barton Jacobs has given $75,000 for a children's unit of the Eudowood Sanatorium which will be for free patients The two story structure, which will be started soon, will be ready for occupancy in the fall

Drs. Bloodgood and Baer Appointed Professors—Dr Joseph C Bloodgood, formerly associate professor of clinical surgery, has been appointed professor of clinical surgery at Johns Hopkins University School of Medicine, and Dr William P Baer, formerly associate professor of clinical orthopedic surgery, has been appointed professor of clinical orthopedic surgery

Baltimore's Ambulance Service—The new ambulance service of the city of Baltimore, placed under the control of the fire department against the advice of the Baltimore City Medical Society and the West Baltimore Medical Society, has been installed and the city divided into five zones, in each of which hospitals have been named to which patients are to be taken Dr Frank N Ogden will supervise the service, twenty firemen have been detailed for duty as orderlies and chauffeurs (The Journal, May 21, p 1648, June 4, p 1819)

MICHIGAN

Personal—Dr Walter C Reineking has been appointed superintendent of Grand View Hospital, Ironwood, to succeed Dr Merlin H Draper——Dr Theophile Raphael, assistant professor of psychiatry, University of Michigan Medical School, Ann Arbor, has been appointed director of the psychiatric clinic in the Recorder's Court, Detroit, to succeed the late Dr Arnold L Jacoby——Dr Charles H Mayo, Rochester, Minn, gave the commencement address at the Detroit College of Medicine and Surgery, his subject was 'Changing Medicine'

State Medical Election—At the annual meeting of the Michigan State Medical Society, Mackinac Island, June 14-17, Dr Herbert E Randall Flint, was elected president, Drs Colin D Munro, Jackson, Charles F DuBois, Alma, Duncan A Cameron, Alpena, and Abram L Van Horn, Otsego, vice presidents, and Dr Carl F Moll, Flint, was elected delegate to the American Medical Association Dr Frederick C Warnshuis, 1508 Grand Rapids National Bank Building, Grand Rapids, is the secretary-editor. The next annual meeting will be held in Detroit

Abortionist Heinl Sent to Penitentiary.—Fred C Heinl, recently convicted at Grand Rapids of manslaughter, was sentenced, June 30, to imprisonment in the state penitentiary for a term of from ten to fifteen years Heinl, an abortionist from Chicago, performed an illegal operation resulting in the death of a young woman The Journal, in May, 1926, called to the attention of the Illinois Department of Registration and Education Heinl's alleged abortion activities carried on from his Chicago address Heinl, who was not a graduate in medicine drummed up trade in Chicago by offering to split fees with druggists who would put him in touch with women who wanted work of this sort done

Policy on Free Clinics—The Kent County Medical Society adopted a resolution, recently, outlining its policy with regard to free clinics as follows:

1 The Kent County Medical Society through its members stands ready at all times to give free medical services to the needy Their interpretation of the "needy" shall be not only the paupers but also those individuals who in the opinion of a trained social worker are worthy of that service

2 The Kent County Medical Society shall have through its committee on clinics a representative on the staff of every organization giving free clinic service So far as possible this representative shall be chosen from such of its members who are at the time serving on clinics

3 The president shall appoint at the beginning of his administration a committee of three to be known as the standing committee on clinics. This committee shall designate its representative on the various clinics These representatives together with the committee appointed by the president shall be known as the conference committee on clinics

4 We recommend, first, that clinics giving free service shall have a trained social investigator, and second, that the records of their investigations shall be accessible to this committee at all times

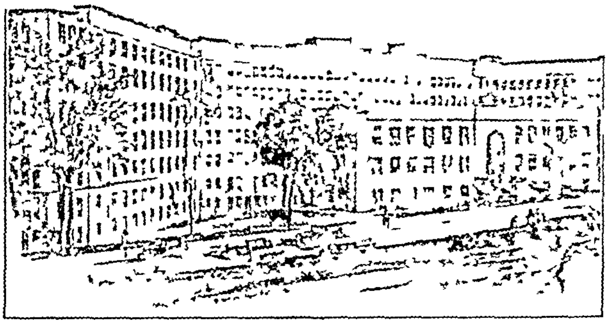
5 This committee shall report from time to time the result of its investigations and make its recommendations to the society

6 The Kent County Medical Society is opposed to the plan that any patient of a free clinic shall pay more than a simple initial fee not to exceed 50 cents and not more than 20 per cent above cost of drugs and supplies

7 The Kent County Medical Society is opposed to the acceptance by its members of any fee for attendance on free clinics conducted on the plan as outlined in this report

8 Realizing the difficulty of establishing an economic standard for free service the committee shall stand ready to cooperate with the social workers in arriving at an equitable and proper solution of these problems

The New University Hospital.—The new building of 700 beds, the old buildings converted into convalescent units with 300 beds, and the contagious unit with fifty beds place the University Hospital at the University of Michigan, Ann Arbor, among the large hospitals of the country The new building is nine stories, concrete, finished in gray brick and stone, and built on the Y and T plan, each room having outside exposure There are 2 miles of corridors and 10 acres of floor space It is a monument to the people of the state, designed and equipped to care for the sick and to teach scientific medicine The first floor is devoted entirely to clinics and clinical service, the south wing of the third floor is for living quarters for about sixty interns The east and west wings of the sixth floor are to be used as wards for children The seventh floor provides a roof garden and occupational therapy storage rooms, and a beautiful view of the Huron River Valley There are amphitheaters and auditoriums, lecture rooms, special laboratories, lounging rooms for visiting physicians and others for students, isolation units, dispensaries, shops and, it appears from the description, all the other accessories and equipment necessary to make the hospital a great center for the care of the sick and the teaching of medicine



MINNESOTA

Society News—The Minnesota Neurological Society met in Rochester, June 11; there was a surgical clinic, five papers were presented by local physicians and an address was given by Dr Monrad-Krohn, professor of neurology, University of Oslo Norway

Personal—Dr Herbert E Chamberlain, White Plains, N Y, has been appointed director of the child guidance clinic of Minneapolis to succeed Dr Smiley Blanton, who resigned to accept a position at Vassar College——The governor has recently appointed Drs Edward W Fahey, St Paul, Howard R Weirck, Hibbing, and William H. Barr, Wells, new members of the state board of health——Dr Alvah W Jones has been appointed health officer of Red Wing to succeed Dr Myron W Smith——Dr Grace G Smith has been elected president of the board of education of Red Wing——Dr James J Swendson has been elected president of the Lions Club of St Paul——Dr Leo G Rigler, Minneapolis, has been appointed roentgenologist at the state university hospital——Dr Rhodric W Browne, who has been charge of the Aberdeen Hospital, St. Paul, has been appointed head of the U. S. Veterans' Bureau Hospital, Fort Bayard, New Mexico

MONTANA

Personal.—Dr. Curtis W. Wilder, Lewiston, has been appointed health officer to succeed the late Dr. Thomas H. Pleasants.——Fred D. Stimpert has been appointed director of the state hygienic laboratory at Helena; Mr. Stimpert formerly was instructor of biology at the University of Montana, Missoula.

NEW HAMPSHIRE

Society News.—Dr. George S. Hazard, Hollis, was elected president of the Hillsboro County Medical Society, April 26; Dr. Alfonse W. Petit, Nashua, vice president, and Dr. Deering G. Smith, Nashua, secretary-treasurer.

State Medical Election.—At the one hundred and thirty-sixth annual meeting of the New Hampshire Medical Society, New Castle, June 22-23, Dr. Emery M. Fitch, Claremont, was elected president; Dr. Joseph J. Cobb, Berlin, vice president, and Dr. Dennis E. Sullivan, Concord, secretary-treasurer Dr. Sullivan was chosen delegate to the American Medical Association. At the annual banquet, Dr. Ezra A. Jones was toastmaster. Among the scientific papers was one by Dr Orrin S. Wightman, New York, and a symposium by Drs. Harlow Brooks and John F. Erdmann, New York, and by Drs Adelbert S. Merrill, Manchester, Howard N. Kingsford, Hanover, and James W. Jameson, Concord. Mrs. Henry H Amsden, Concord, was elected president of the woman's auxiliary Mrs. John O. McReynolds, Dallas, Texas, president of the National Woman's Auxiliary, attended the meeting.

NEW MEXICO

Personal.—Dr. Howard W. Heymann, Raton, has been appointed part-time health officer of Colfax County, to succeed Dr. Augustus B. Stewart.——Dr. Albert J Hoskins, formerly commanding officer, U. S. Veterans' Hospital, Fort Bayard, has been transferred to Phoenix, Ariz.; Dr. Rhodric W. Browne, St. Paul, will take charge at Fort Bayard

Public Health Association.—The third annual meeting of the New Mexico Public Health Association was at Taos, June 2-3; among others, Dr. Meldrum K. Wylder, Albuquerque, spoke on "Breast Feeding of Infants" Dr Charles W. Gerber, Las Cruces, led a round table discussion on the control of German measles and chickenpox, and Dr. Cranford H. Douthirt, Clayton, one on cooperation with the medical profession, and Dr. Owen E. Puckett, Carlsbad, one on the medical examination of food and drug handlers. Dr. Dudley B. Williams, Santa Fe, discussed "Standardization of Record Forms for Full-Time County Health Units," and Dr. I. O. Church, "County Health Work in Kansas."

NEW YORK

Personal.—Dr. George H Whipple, dean and professor of pathology, University of Rochester School of Medicine and Dentistry, was awarded the honorary degree of doctor of science, recently, by Colgate University——Dr. Helen L. Palliser, Poughkeepsie, has been elected secretary of the Medical Women's National Association

Society News.—Dr. Harry R Trick, president-elect, Medical Society of the State of New York, was guest of honor at the annual meeting of the Genesee County Medical Society, Dansville, June 24——Members of the Medical Society of the County of Erie offered their fifth program of instruction on heart disease, June 9, at Alumni Hall, University of Buffalo, when among the papers read were those by Dr. John H Wyckoff, Jr., New York, and Dr. William D. Stroud, Philadelphia.

New York City

Dr. Mosher Honored.—Dr. Eliza M. Mosher, one of the earliest women graduates in medicine, turned the first spadeful of earth, June 18, for the new women's building, University of Michigan, Ann Arbor, for which the alumni have collected $1,000,000 in the last five years Dr Mosher was for years dean of the women students and the first full-time women professor on the faculty The hostess room in the women's building will be named in her honor.

Personal.—Dr. William F. Wild has resigned as field representative of the American Society for the Control of Cancer, and Dr. Raymond V. Brokaw, superintendent of health of Springfield, Ill, has been appointed to fill the vacancy——Dr. Frankwood E Williams received the honorary degree of doctor of science from Colgate University at the recent commencement.——Dr. Harlow Brooks has been appointed professor of internal medicine at the Polyclinic Medical School and Hospital.

Meeting of Orthodontists.—The Alumni Society of the Dewey School of Orthodontia will meet, August 29-31, at the Hotel Vanderbilt, for a series of clinics and lectures. Clinics will be given by several men from New York and from Nashville, Tenn Homer B. Robison, D D.S, Great Bend, Kan, will lecture on "Some Erroneous Diagnoses of Acromegaly" and "Endocrines—Their Effect on the Osseous, Genital and Mental Development in Relation to Orthodontics", other speakers will be Samuel E Pond, Ph D, University of Pennsylvania School of Medicine, Philadelphia, "Physical Consideration Concerning the Alleged Stability of Bone and Similar Structures", Moe B Markus, D D S, Philadelphia, "Review of the Literature on the Influence of Habits in Orthodontia"; Albert C Holzman, D.D S, Boston, "Orthodontia of Deciduous Teeth," and Russell E. Irish, D D S, Pittsburgh, "Mental Orthodontia—Its Stimulants and Depressants"

Changes in Personnel at Rockefeller Institute.—Among the changes in personnel of the scientific staff of the Rockefeller Institute for Medical Research are the following:

APPOINTMENTS

Dr Carl Ten Broeck, professor of bacteriology, Peking Union Medical College, Peking, China, member
Arthemy A Horvath, associate in chemistry in the department of medicine, Peking Union Medical College, Peking, China, associate.
Dr Mortimer L Anson, assistant.
Dr Allan M Butler, assistant
Dr Claude E Forkner, assistant.
Dr Alvin R Harnes, assistant.
Dr Perrin H Long, assistant
Dr Alfred E Mirsky, assistant.
Dr Gordon H. Scott, assistant

PROMOTIONS

Dr Thomas M Rivers, associate member to member.
Dr Carl A L Binger, associate to associate member.
Dr Leslie T Webster, associate to associate member.
Dr Lillian Baker, assistant to associate
Dr Lawrence S Kubie, assistant to associate.
Dr Fred W Stewart, assistant to associate

Robert T Hance, Ph D, has resigned to become professor of zoology, University of Pittsburgh, Pittsburgh

Two Brooklyn Hospitals Consolidate.—The Brooklyn Eye and Ear Hospital and the Williamsburg Hospital have consolidated after two years of consideration and will continue under the name of the Brooklyn Eye and Ear Hospital. There probably will be erected a seven story, fire-proof, $1,500,000 structure on Green Avenue extending the whole width of the block from Cumberland Street to Carlton Both hospitals were founded about fifty years ago, the Williamsburg Hospital was consolidated with the Eastern District Hospital and Dispensary in 1916 and it closed its doors in 1920 The Brooklyn Eye and Ear Hospital was organized in 1864 on the present site of the Brooklyn Post Office, but soon moved to larger quarters on Washington Street, now the site of the approach to the Brooklyn Bridge Since 1882, it has been at 94 Livingston Street and has averaged about 120,000 dispensary cases a year Several years ago it sold the building and purchased a site for a new home at Green, Cumberland and Carlton streets, where it is expected the consolidation of the two hospitals will make it possible to proceed with the building program of the Brooklyn Eye and Ear Hospital, which has been postponed on account of the rising cost of construction.

NORTH CAROLINA

Society News.—Dr James M Parrott, Kinston, addressed the Wake County Medical Society, Raleigh, June 9, on "Business Relations of the Medical Profession"——The seven sanitary experts and inspectors of the state board of health loaned to the flood refugee camps were recalled to their duties in North Carolina, June 15

Annual University Extension Courses.—The seventh annual summer courses of the extension division of the University of North Carolina School of Medicine is being given in the following centers: Wilmington, Fayetteville, Rocky Mount, Kinston, Greenville and Hamlet The lectures and clinics are in pediatrics and general medicine, each class meeting once a week for twelve weeks The instructor in pediatrics is Dr Alexis F Hartmann, St Louis, associate professor of pediatrics, Washington University Medical School, and the instructor in general medicine is Dr. Charles L Brown, instructor in medicine, Harvard University Medical School The program is arranged so as to permit physicians to attend the courses with the least amount of disturbance to their practice. The arrangement has proved unusually successful, and has come to be known and referred to in other states as the North Carolina Plan.

Hospital News.—The improvement to be made at the state hospital for colored insane, Goldsboro, included the replacement of the wooden building for tuberculosis cases with a fire-proof structure costing about $110,000.——Judge Sinclair, presiding at Kinston, in interpreting the report of the grand jury in regard to the insanitary conditions of county institutions, ordered the indictment of the responsible county officials unless the institutions were placed in sanitary condition at once.——The new Candler-Tidmarsh Hospital, Sylva, was opened for patients, May 20.——The new $100,000 Greensboro Hospital for Negroes was formally opened, May 24; half of the cost of the institution was donated by the family of the late Lunsford Richardson, the remainder being given by many citizens of the community. The roentgen-ray equipment, representing an investment of $7,800, was presented by Mrs. E. Sternberger. The hospital is complete and modern in every respect.——The Charlotte Hospital Association, organized, June 11, with Dr. Robert T. Ferguson, president, is composed of all the larger hospitals in Mecklenburg County. Quarterly meetings will be held.

NORTH DAKOTA

Society News.—At the annual meeting of the North Dakota Academy of Ophthalmology and Oto-Laryngology, Grand Forks, May 31, Dr. Rolfe Tainter, Fargo, was elected president to succeed Dr. Andrew M. Carr, Jr., Minot. The meeting included a banquet, and scientific and business sessions. The visiting clinician was Dr. Frank E. Burch, St. Paul.

PHILADELPHIA

University News.—The Woman's Medical College of Pennsylvania held its seventy-fifth annual commencement, June 9; degrees were given to fourteen graduates, six of whom will go to foreign medical missionary service after completing their internships.

Hospital News.—The assets of the old Roosevelt Hospital, which was sold in 1924, have been donated to Temple University, and will be devoted to the completion of the fourth floor of the Samaritan Hospital, the construction of rooms and the conversion of private rooms in the old building into public wards. The additional floor will be known as the Roosevelt Memorial floor of the Samaritan Hospital.

Annual Heart Demonstration.—A demonstration in cardiac diagnosis and treatment was given, May 23-26, by the Philadelphia Heart Association cooperating with the Pennsylvania Heart Association, which was practically identical with the two previous annual demonstrations. Thirty-three physicians from over the state attended, whereas the first one in 1925 had an attendance of fourteen and the second in 1926 of twenty-seven. The increased interest makes it desirable to continue the demonstrations each year, with the object of establishing heart clinics throughout the state where persons unable to afford competent care will be thoroughly studied. Demonstrations were made at the University of Pennsylvania and Temple University, at Jefferson Medical College, the Children's Heart Hospital and the Presbyterian Hospital by teachers well known in this line of work and were so arranged as to allow each person present to see at least one heart clinic in operation.

Personal.—Dr. Chevalier Jackson gave the address at the fifty-seventh commencement at Ursinus College, Collegeville, June 6. Dr. Jackson has presented the casket, gold medal and scroll, constituting part of the Bok Award recently received by him, to the College of Physicians of Philadelphia.——Dr. Orlando H. Petty was nominated without opposition for president of the Philadelphia County Medical Society, June 15, and his election will automatically follow in November.——Dr. Valentine R. Manning was guest of honor at a testimonial dinner at the Elks Club, June 15, attended by about 400 friends.——Dr. George E. de Schweinitz, Past President of the American Medical Association, received the honorary degree of doctor of science from Harvard University at the commencement, June 23.——Dr. Hobart A. Hare, professor of therapeutics, materia medica and diagnosis, Jefferson Medical College, was guest of honor at a dinner at the Schuylkill Country Club, Pottsville, June 14.

Firemen Honor Dr. Da Costa.—The firemen of Philadelphia have donated $2,000 to the building fund of Jefferson Medical College in honor of Dr. John Chalmers Da Costa, professor of surgery, Jefferson Medical College, who, for about thirty-five years, gratuitously served as surgeon of the fire bureau, surgeon of the Firemen's Pension Fund and in other capacities. A similar amount was contributed from the sheriff's office in honor of Dr. Da Costa and both funds will be used jointly to establish a memorial to him. It appears that Dr. Da Costa's devotion to the fire bureau is a family trait, as his grandfather was a member of the Northern Liberties Volunteer Fire Engine Company, his father a member of the Philadelphia Hose Company, and his uncle, a member of the Phoenix Hose Company. For about thirty-five years, Dr. Da Costa never failed to attend a fire of any importance in the city. The fund was given by the members of the department, many of whom he had attended at the scene of a fire. Physical disability compelled Dr. Da Costa to resign as surgeon of the Firemen's Pension Fund about seven years ago, although he still holds the position in an honorary capacity.

TENNESSEE

Health at Memphis.—Telegraphic reports to the U. S. Department of Commerce from sixty-seven cities with a total population of about 30 million, for the week ending June 25, indicate that the highest mortality rate (19.2) was for Memphis, and that the mortality rate for the group of cities as a whole was 11.2. The mortality rate for Memphis for the corresponding week last year was 25, as estimated by the arithmetical method, and for the group of cities, 11.2.

Malaria in Tennessee.—During 1926, there were 1,686 cases of malaria in the state, an increase, according to the Tennessee Department of Public Health, of 306 cases reported; in 1925 there were 159 deaths from malaria. Of the cases reported last year, 68.3 per cent were in West Tennessee. Six of the twenty counties in that portion of the state have whole-time health service. As the waters of the flood recede and the homes are rehabilitated in that section, the malaria problem will become more serious. The chief weapons of defense against malaria are quinine prophylaxis and the screening of carriers. One county in West Tennessee requested 21,000 capsules of quinine in a single order, and three counties have a standing order of a shipment of 32,100 capsules a week. The screening of carriers and general screening operations will be carried out with the cooperation of the U. S. Public Health Service officials.

WEST VIRGINIA

Hospital News.—Dr. Mortimer D. Cure has retired from the staff of the Weston State Hospital for the Insane at Weston and has been succeeded, temporarily, by Dr. John G. Pettit from the Hopemont Tuberculosis Sanatorium.

State Medical Election.—At the sixtieth annual meeting of the West Virginia State Medical Association, White Sulphur Springs, June 21-23, Dr. Charles A. Ray, Charleston, was elected president; Drs. Desausseur G. Preston, Lewisburg, Edward L. Armbrecht, Wheeling, and Walter C. Swann, Huntington, vice presidents, and Dr. Thomas M. Barber, Charleston, treasurer. The new executives take up their duties, Jan. 1, 1928. Mr. Joe W. Savage was reelected executive secretary of the association; Dr. James R. Bloss, Huntington, editor of the journal; Dr. Raymond H. Dunn, South Charleston, a chairman of the council; Dr. Henri P. Linsz, Wheeling, delegate to the American Medical Association. The members considered at this meeting a plan of erecting a permanent home for the society at Charleston and were of the opinion that in a few years the permanent headquarters would be established.

WISCONSIN

Personal.—Dr. John L. Yates, Milwaukee, was elected vice president of the American Association for Thoracic Surgery, New York, May 11.——Dr. Fred E. Tryon has been appointed health officer of Baraboo.

Society News.—Dr. George F. Dick, Chicago, addressed the Milwaukee Pediatric Society at the Milwaukee Children's Hospital, June 8, on "Scarlet Fever," and Dr. Karl E. Kassowitz, Milwaukee, on "Bactericidal Effect of Quartz Light."——Dr. Ralph W. Webster, clinical professor of medicine and medical jurisprudence, Rush Medical College, Chicago, addressed the Brown-Kewaunee County Medical Society, Green Bay, May 3, on "Malpractice."——Among other speakers before the Grant County Medical Society at Boscobel, May 10, were Drs. Edward W. Alton Ochsner, professor of surgery, University of Wisconsin Medical School, Madison, on "New and Simple Methods of Chest Diagnosis," and James H. Fowler, on "Relation of the Specialist to the General Practitioner." The society had dinner with the Boscobel

Kiwanis Club; at the election of officers, Dr. Charles S. Hayman was made president for the ensuing year.

Fifth District Meeting.—The Fifth Councilor District Medical Society held its annual meeting, June 30-July 1, at Elkhart Lake, where there are facilities for golfing, boating, tennis, fishing and swimming. Drs. Wilber E. Post and Paul B. Magnuson, both of Chicago, read papers on "Diseases of the Kidney" and "Treatment of Fractures," respectively; Drs. George V. I. Brown, Madison, spoke on "Plastic Surgery as Related to Practitioners of General Surgery"; Joseph P. McMahon, Milwaukee, "Experiences and Responsibilities of the Medical Profession with the Cancer Problem"; Otto H. Foerster, Madison, "Ringworm Infection of the Hands and Feet; a Common and Usually Unrecognized Dermatosis"; Friedrich Eigenberger, Sheboygan, "Experiments with Rattlesnake Venom," and Cornelius A. Harper, Madison, "Periodic Examinations of the Apparently Healthy." Following the banquet, Thursday, Glenn Frank, president, University of Wisconsin, and Dr. Arthur W. Rogers, president of the state medical society, gave addresses.

GENERAL

Society News.—At the annual meeting of the American Psychopathological Association, June 3, Cincinnati, Dr. Ross M. Chapman, Towson, Md., was elected president and Dr. Martin W. Peck, Boston, secretary. The next annual meeting will be held at Minneapolis.

Birth Rates Lower—Death Rates Higher.—In twenty-six of the twenty-eight states for which figures for the two years are available, the birth rates were lower for 1926 than for 1925, the department of commerce announces. Florida had the highest birth rate (26.4 per thousand of population) for 1926, and Montana the lowest (14.2). In twenty-three of the twenty-eight states for which figures are available for both years, the death rates for 1926 were higher than for 1925. Florida had the highest death rate (15.3 per thousand of population) and Montana the lowest (7.8). Twenty-one of the twenty-eight states showed higher infant mortality rates also for 1926, with Delaware the highest, 92.9, and Oregon the lowest, 51.6.

Ten Years of Bovine Tuberculosis Work.—In the ten years of the campaign to eradicate bovine tuberculosis from dairy herds of the United States, about 30 million cattle have been tested for tuberculosis and about 1 million of them have been destroyed. During this period, the annual consumption of milk in this country has increased more than 49 quarts per capita. During 1926, the U. S. Department of Agriculture notes that the public consumed 56 billion pounds of milk and cream. Cities and towns have become aware of the importance of better milk and 874 of them have adopted ordinances requiring tuberculin testing of cattle; in addition, 375 cities and towns provide an option between tuberculin testing and pasteurization. Thus 1,249 municipalities have taken positive steps to safeguard their milk supply.

Reorganization of Food and Drug Administration.—The U. S. Department of Agriculture announces that the new unit known as the Food, Drug and Insecticide Administration will become effective, July 1; W. G. Campbell will be in charge. Congress created the Food, Drug and Insecticide Administration recently for the purpose of separating work involving scientific research from the work of law enforcement. The new arrangements involve no change in the policy of enforcement and other acts concerned. The laboratories of the Bureau of Chemistry that are now engaged on food and drug control work will operate under the new unit. Mr. Campbell was a lawyer before joining the department of agriculture about twenty years ago. P. B. Dunbar, Ph.D., the assistant chief of the new unit, entered the service of the Bureau of Chemisty in 1907, and since 1925 has been assistant chief of the bureau.

Mosquito Eradication in Southern Salt Marshes.—The U. S. Public Health Service, under a special appropriation made by Congress, has been conducting surveys of the salt marshes of the South Atlantic and Gulf States in order to devise economical means of eradicating mosquitoes. These studies made in various states show the magnitude of any plan necessary to eliminate the breeding of salt marsh mosquitoes. These marsh areas range from 33,361 acres in one Southern state to 3,381,514 acres in another state. In studying methods to destroy mosquitoes in salt marshes, the factors to be investigated include the breeding and flight of the species of mosquitoes encountered, the type of vegetation found in the marsh area, the character of the soil, acreage of marshes, information on drainage, filling and the construction of sea-walls, the making of maps and collection of climatological data. Detailed studies of these factors are necessary to determine economical means of preventing the breeding of mosquitoes in these marsh areas. One fact brought out in a survey was in regard to the general distribution of *Anopheles atropos*. An observer had classed this species of mosquito as a mud breeder. The Public Health Service demonstrated that this mosquito breeds not only in muck pools in salt marshes, but in salt marshes in clear water. In several locations, the adults of this species were found to be more numerous than other types of salt water breeders and they were found to enter houses and bite freely by night and by day.

National Committee for Prevention of Blindness.—The twelfth annual report of this committee contains a tabulation which indicates that the amount of blindness due to ophthalmia neonatorum in schools for the blind decreased from 23 per cent during the period 1908-1912 to 12.5 per cent during the period 1923-1926. During the last year the national committee conducted two joint sessions with the American Social Hygiene Association on the subject of "Relation of Venereal Diseases to Vision Impairment." Some of the most prominent ophthalmologists, syphilologists and public health officials participated in these conferences. The committee sponsored the establishment of preschool eye clinics, and at the end of 1926 this work was being carried on in three demonstration centers, where children between 3 and 6 years of age had their eyes inspected and examined when necessary. The report notes that the sight-saving classes in the United States have increased from two in 1913 to 265 in 1926. This work, aside from promoting public interest in sight-saving, concentrates on two special projects: the conducting of courses during the summer sessions on eye hygiene and methods of sight-saving class work at the University of Cincinnati, and a brief survey of schools for myopic persons in Great Britain. The committee continued to promote the use of mechanical devices in industries to save sight; to educate employers and other officials in the necessity for these devices, and to provide adequate light and sanitary facilities in industry. The honorary president of the committee is William Howard Taft, and the managing director, Lewis H. Carris The headquarters office is at 370 Seventh Avenue, New York.

CANADA

Personal.—Drs. Judson V. Graham and Victor O. Mader have been appointed on the staff of the Dalhousie Clinic to fill vacancies caused by the death of Dr. Vernon L. Miller and the resignation of Dr. Philip Weatherbe.——Dr. Edward W. Archibald, director and professor of the surgical department of McGill University Faculty of Medicine, was recently made an honorary fellow of the Royal College of Physicians of London; Dr. Archibald is the fourth Canadian to be thus honored.——N. B. Dreyer, assistant professor of physiology, Dalhousie University Faculty of Medicine, has resigned to accept an appointment in the department of pharmacology at McGill University Faculty of Medicine, Montreal.

Traveling Health Clinic.—The clinic organized by the minister of health, the Hon. Mr. Hoadley, started, May 15, to visit 120 rural communities which have voluntarily requested a visit. The clinical personnel will examine school children and any other person free of charge, and when necessary will perform minor operations, making a nominal charge for those able to pay. The *Journal of the Canadian Medical Association* says there is a physician, an anesthetist, a dentist and two nurses in the party, and a second physician follows up, remaining on call in a community for twenty-four hours, to be present in case of any complications following a minor operation. The clinic will be out for about four months. The equipment and personnel are carried in two automobiles.

Society News.—Dr. Austin B. Schinbein was elected president of the Vancouver Medical Association at its twenty-ninth annual meeting, April 19, Vancouver; Dr. George F. Strong, secretary, and Dr. Anson C. Frost, treasurer.——At a joint meeting of the British Columbia Medical Association and the Vancouver Medical Association, Vancouver, June 22, Dr. Benjamin P. Watson, New York, was the principal speaker.——Dr. James G. McKay, Vancouver, addressed the May meeting of the Victoria Medical Society on "Paranoidal States of Interest to General Practitioners."——At the twentieth annual meeting of the Academy of Medicine of Toronto, May 3, Dr. John H. McConnell was elected president. The library of the academy is the second largest in Canada, having 8,500 volumes and about 250 current medical journals. The present membership of the academy is about 862.

LATIN AMERICA

Costa Rica Creates Health Department.—A cablegram received from Dr. Solon Nunez, secretary of State of Costa Rica, states that a national department of public health and public welfare has just been organized in Costa Rica. Costa Rica thus becomes the sixth Latin American country to recognize the importance of public health matters by placing them in exclusive charge of a member of the cabinet. Bolivia, Chile, Cuba, Honduras and Santo Domingo had already acted to the same effect. Dr. Solon Nunez, the head of the former health bureau, becomes the first incumbent of the newly created position.

Hospital Laboratory Dedicated.—The Presbyterian Hospital, San Juan, Porto Rico, has converted one floor of the hospital into clinical and research laboratories, which were formally dedicated recently. Dr. James W. Jobling, professor of pathology, Columbia University School of Medicine, New York, and Dr. Robert A. Lambert, director, School of Tropical Medicine, were guests of honor at the ceremonies. The laboratories are equipped for all modern diagnostic procedures. The director, Dr. Charles Weiss, of the department of bacteriology of the School of Tropical Medicine, was formerly a fellow in medicine of the National Research Council studying at Columbia University.

FOREIGN

Unusual Study of Children.—The Malting House, Cambridge, England, desires to obtain the services of a scientist of the first order, as young as possible, with a knowledge of the theory of science to investigate and conduct the introduction of children to science and scientific methods. To obtain the services of a suitable scientist, a salary will be paid such as will enable him to leave his present occupation whatever that may be. Preliminary work with young children (from 4½ to 7 years of age) has already been done at the Malting House School. It has encouraged the directors to make a full-time, long period appointment to develop this work, and they hope it will be the beginning of a research institute into problems connected with education. They desire a man of outstanding suitability, not necessarily a specialist in his own branch, acquainted with other sciences, the history of science and the history of religious beliefs. The problem involves in part an investigation by delicate observation of what sort of activities are best introduced into the child's environment and what should be the order of opportunity for these activities; further, the question of whether there exists any special factors limiting or making undesirable the introduction of children of such tender age to scientific knowledge and scientific thought. The work involves also developing a technic to utilize the child's native curiosity in such a way as in the long run to obtain the maximum conversion of his native curiosity into a controllable instrument of organized thought. The directors will be assisted in selecting the scientist by Prof. Sir Ernest Rutherford, Prof. Percy Nunn and Mr. J. B. S. Haldane. Communications should be addressed to The Directors, The Malting House, Cambridge, England.

Government Services

Graduation at Army Field Service School

The class in the eighth basic field course at the Army Medical Field Service School, Carlisle Barracks, Pa., graduated, May 28. Brig. Gen. Frank R. Keefer, assistant surgeon general, gave the principal address and presented the Skinner Medal for the highest standing in the class to Lieut. George E. Armstrong, medical corps. There were six other honor graduates, one of whom was from the veterinary corps. The total enrolment in the class was fifty-eight, including medical, dental and veterinary officers; one officer of the navy, two of the Cuban army and one each of the dental corps and the Philippine Constabulary. Lieut. Col. Charles R. Reynolds, commandant of the school, presented the diplomas.

Reserve Officers Assigned to Flood Duty

The following reserve assistant surgeons of the U. S. Public Health Service were assigned to duty at New Orleans in connection with flood work, June 11:

Edmund T. Lentz
W. J. Bryan McAuliffe
William W. Nesbit
Leon O. Parker
Charles B. Stacy
Joseph F. Van Ackeran

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 18, 1927.

Opticians Fail to Obtain Recognition by the Government

The attempt of the osteopaths to obtain state recognition ended in failure. A similar attempt by another body of irregular practitioners has met the same result. In the house of commons was moved the second reading of a bill to secure the registration of optical practitioners and to regulate the practice of sight-testing. It was proposed to set up a central optical board of Great Britain with power to register persons, after evidence of qualification, as optical practitioners. The mover of the bill said that every state of the United States had laws controlling and directing opticians. The Americans were probably the most bespectacled people in the world. That was not because their eyesight was worse than that of other peoples but because they recognized the fact that eyesight was important and took precautions to preserve it. That fact was also coming to be more and more recognized in this country. More spectacles were being worn by adults and children in this country than were worn eight or ten years ago, not for the reason that the eyesight of the country was worse but because of the efforts of opticians to cope with the problem. In the Council of the British Opticians and the Council of the Worshipful Company of Spectacle-Makers there was a registration of 3,500 opticians, of whose qualifications some guarantee was given. Opposition to the bill came from the unqualified opticians and the medical profession. There were at present a large number of quacks and venders of spectacles who had neither the apparatus nor the ability to test eyesight, and there had grown up something of a vested interest which would be affected if this bill became law. There were, however, many opticians who, though unqualified, had had long experience in this particular kind of work but who might have difficulty in satisfying the tests that were suggested in the bill. There was nothing in the bill to hinder any one who was now carrying on work as an optician continuing to do so. All the bill would do would enable the public to distinguish between men with regard to whose qualifications some guarantee was given by the board set up under its provisions and those whose qualifications could not be vouched for by a responsible organization. It was said that only 5 per cent of the cases of defective eyesight were due to some disease of the eye or disease arising from some other cause, and the opposition of the medical profession was based on what it feared would be the danger to this percentage from the registration of opticians who, though they might be perfectly qualified to test the sight and to prescribe the appropriate glasses, had not the training necessary to enable them to diagnose the cause of the trouble in the eye.

A physician, Dr. A. V. Davies, moved an amendment, "That the House declines to give a second reading to a bill the subject matter of which is at the present time being investigated by a departmental committee." He said that the promoters of the bill asked that a body of unqualified men, with a certain amount of training, which might be limited or otherwise, should have state approval of their profession. If they were successful in their demand, it would mean that the public would regard them as competent to examine and treat eyes, and that was a position which could not be maintained. Sir George Berry, the ophthalmic surgeon of Edinburgh, in seconding the amendment, said that legislation on the lines proposed would not be in the real interests of the public. In his experience, which was fairly considerable, he had never known a case in which spectacles, however unsuitable, did any harm to the eyesight. There was such a thing as considerable discomfort being caused by unsuitable spectacles, as there was in the wearing of ill fitting boots or a nonfitting dental plate, but it was an exaggeration to say that there was any actual danger to the eye from that source. Although spectacles, even if unsuitable, did not do harm, they were, if they were suitable, capable of doing a great deal of good. That, to his mind, was a justification for the public having the services of skilled opticians, but it did not, in his view, justify the kind of legislation proposed by this bill, which was calculated to mislead the public and to arouse a mistaken and, therefore, an undesirable degree of security. The optician might be able to detect the existence of disease, and, perhaps, to discriminate, in some cases, between diseases of the eye; but he could not do so without being liable to make a great many mistakes unless he had had the full training of a physician. Sir Kingsley Wood, parliamentary secretary of the ministry of health, said that the prevalence of defective sight among school children was about 10 per cent. In the population generally it could be roughly estimated that the number of persons with defective sight in England and Wales was about one in five. There was undoubtedly a case for something to be done, but there was considerable divergence of opinion as to how it should be done. Physicians had urged with a considerable amount of weight that there was an appreciable percentage of cases in which great harm might be done by an ophthalmist through lack of medical knowledge, but how far that argument was valid could be ascertained only by full investigation of the facts. It was all the more important that there should be an impartial inquiry because of the large amount of money now being spent by approved societies on optical benefits. He suggested, therefore, that the matter should be referred to a departmental committee. The motion for second reading was negatived without a division.

Clean Milk

An important discussion on clean milk took place at the Surrey County Hospital, Guildford, where a joint meeting of the medical and veterinary professions was held. Professor Hobday, honorary veterinary surgeon to the king, urged that the eradication of tuberculosis from nearly a million milch cows in this country was a question not only of cost but also of expediency. At present there were many hundreds of milking sheds in which the inspector appointed by the ministry of health, usually a physician, had never set foot, and often the official inspector, even if he tried to perform his duties properly, had no practical knowledge of what he was supposed to inspect. Such inspection was obviously the job of the veterinarian, and it seemed anomalous in 1927 to find the work being attempted by the health officer or the sanitary inspector. For satisfactory inspection the inspection board should have a health officer, a veterinary officer of health and a sanitary inspector. Each would find plenty to do in his own legitimate sphere, and neither would overlap the work of the other. Professor Hobday also drew attention to the astonishing apathy and ignorance of the public in regard to clean milk and the consequent need for education, which could be given only by the medical and veterinary professions.

Dr. Nathan Raw, president of the Tuberculosis Society of Great Britain, thought it to the discredit of this country that, after twenty-five years' work, from 10 to 12 per cent of the samples taken of our milk supply still contained tubercle bacilli. He was a stanch advocate of the production of clean milk in the first place, but this was for the most part an unattainable ideal at the present time. He therefore had been reluctantly converted to pasteurization as the only possible way of guaranteeing safe milk for our great urban population. Mr. Male, a veterinary inspector, said that farmers could produce clean milk if the public would pay for it. If only the milk and dairies act were properly administered throughout the country we should hear little about dirty milk. The need for pasteurization would not exist, since in a short time only clean milk from tuberculous free herds would be produced. Dr. Howell, health officer for Hammersmith, said that the superior safety of London's milk at the present time was reflected in a big reduction in infantile troubles. Owing to the uncertain conditions of milk production, pasteurized milk was the only safe form. A representative from Reading University urged the meeting to rebut the statement so often heard that clean milk—that is, the higher grades of milk—was an expensive luxury. The production of clean milk was not a question of expensive and elaborate sheds and equipment but of method. Pasteurization might destroy the noxious germs in milk, but it could not make dirty milk clean. It was just as easy to produce a clean product as a dirty one. All that was required was education first of the farmer and secondly of the public, who must be taught to buy clean milk at a fair price.

The World's Hospitals

The results of an extensive tour of hospitals in Europe and America were submitted to the Royal Institute of British Architects by Mr. Lionel G. Pearson, F.R.I.B.A. He was confident that no country had finer hospitals than England, but there was much to be learned from other countries. There are some critics who would say that in Europe the comfort of the patient is the first consideration, while in America the efficiency of the staff is; but the two points of view seem to be of almost equal importance to the hospital planner. The science of hospital planning was pursued very successfully in all the countries visited, and there was a friendly rivalry to produce buildings which are down to date from the point of view of medical science, and, at the same time, attractive to the patient. Mr. Pearson was cheered to find in his journeys that some of the difficulties that beset hospital architects in this country are apparently universal; for instance, he never met a sister who was really satisfied with the accommodation provided for linen, or found a type of window that admitted fresh air without causing a complaint from some patient in the ward. Dealing with the American part of his tour, Mr. Pearson said that the number of hospitals which had been built during the last ten years was amazing. The multistoried hospital was the most popular just now. This has led to the vertical type of planning, with the elevator, the laundry chute, and various other labor-saving devices. The long corridors of the European hospital are considered quite out of date, and one American visitor remarked, after seeing one of our hospitals, that he hoped the staff were fitted with roller-skates. The entrance was made as attractive as possible and the waiting room furnished like a hotel lounge; the anesthetic room was frequently furnished like an ordinary room to avoid "the operation atmosphere." The increasing importance of roentgen-ray work was nowhere more fully recognized than in America, where its use for diagnosis had reached such a point in one important hospital more than 85 per cent of the patients were now roentgenographed. The large ward seemed to be a thing of the past, and smaller units are now the rule everywhere.

The World's Finest Dental Clinic for London

London will soon possess the world's finest dental clinic. This will be due to the generosity of Mr. George Eastman of Rochester, N. Y., and head of the Kodak Company, who is giving $1,500,000 in order to establish the clinic in London. Mr. Eastman has for many years taken a great interest in dentistry, and particularly in the care and improvement of children's teeth. Ten years ago he established a clinic in Rochester, N. Y., under the direction of Dr. Harvey J. Burkhart. Dr. Burkhart is in London making the arrangements for the establishment of the new clinic. It will contain fifty chairs in the main infirmary and seven in the orthodontia department. There will also be twenty-five beds for tonsils, adenoids and cleft palate cases, for which at present there is a great scarcity of beds in London.

Visit to London of the Inter-State Post-Graduate Assembly of North America

The Inter-State Post-Graduate Congress has held a three-day session, including lectures and visits to various London hospitals. A lecture on gallstones was given by Sir Crisp English. Dr. L. S. T. Burrell gave a lecture on shock tactics in pulmonary tuberculosis. Visits were paid to the Middlesex Hospital, Charing Cross Hospital, the London Temperance Hospital, and St. Paul's Hospital for Skin and Genito-Urinary Diseases. At each of these institutions, demonstrations and lectures were given.

PARIS

(From Our Regular Correspondent)

June 1, 1927.

Meeting of the General Association of French Physicians

The Association générale des médecins de France held last week in Paris, in the large amphitheater at the Faculté de médecine, its seventy-fifth general assembly since its foundation. Ninety-four constituent local associations sent delegates. The association comprises 10,060 members, 566 having been added this year, but from this number 263 must be deducted by reason of deaths. It has, since the last report, distributed 214,404 francs in the form of benefits in aid of 342 physicians or their families, and has, in addition, accorded pensions to 174 of its aged or disabled members. The local societies all have their own independent treasury for social welfare work, but they send each year to the general treasury one tenth of the dues that they collect (the dues range from 16 to 60 francs, according to the region), and, in addition, a fixed sum of 5 francs per member. The association received considerable endowment from the estate of D. Benoit of Montauban, who was, however, not a member. Among the subjects discussed by the general assembly were the proposal to create a council on medical ethics, the publication of a code of medical ethics, and the publication of a memorial volume dedicated to the physicians killed during the war. The closing banquet took place in the halls of the medical arts building (*foyer médical*), which was dedicated on that occasion, although not fully completed as yet nor opened to its members. At the banquet M. André Fallières, minister of public health, presided.

The Inquiry on Cancer

An extensive inquiry has been opened on cancer and all the physicians of France have been requested to address to Professor Hartmann, president of the league against cancer, their personal opinions, on the basis of their observations of their patients, on the following three questions: (1) the hereditary transmission of cancer; (2) the contagiousness of cancer, and (3) its relations to other diseases. The medical journals have already begun the publication of some of the more interesting replies in order to stimulate the zeal of others. It is apparent from the fraction of replies already received that many physicians believe in the hereditary transmission of cancer but that they hesitate to admit its contagiousness, not having observed any convincing examples. It is evident also that many assign to syphilis, and even to tuberculosis occasionally, a predisposing rôle. Dr. Dorvaux of St. Denis urges that the posters put up everywhere by the league warning against the dangers of cancer should contain also a warning against the claims of quacks concerning pharmaceutical products with which patients vainly treat themselves and thus allow the (often brief) period to slip by within which they might, with good hope, have recourse to the surgeon or to the radiologist for an early diagnosis that would serve as the basis for efficacious treatment. Unfortunately, there is in France no official control of advertisements of remedial agents; consequently, the quacks who exploit such remedies or who create so-called cancer institutes do a prosperous business.

The Centenaries of Vulpian and Pinel

The ceremonies in honor of the centenaries of Vulpian and Pinel, which were held simultaneously in spite of the fact that these scientists, a physiologist and an alienist, were devoted to quite different fields of research and that a gap of a century intervened between the two men, extended over a whole week but were not attended by many besides the official personages, owing to the distraction occasioned by the flight of Lindbergh. Friday, May 27, and Saturday, May 28, there was a plenary assembly of the Société de biologie and its affiliated societies. Saturday evening, in the large amphitheater of the Faculté de médecine, there was a formal meeting presided over by M. André Fallières, minister of public health, and supported by presidents of the large learned societies and numerous official foreign delegates. Dr. Fano, *"senatore del regno,"* spoke in the name of the latter. M. Roger, dean of the Faculté de médecine, recounted the scientific career of Vulpian, who was likewise dean of the medical faculty. M. Lacroix, as the representative of the Academy of Sciences, and M. Rathery, who occupies, at present, in the medical faculty, the chair formerly held by Vulpian, told of his researches in experimental physiology and of his great friendship for Pasteur, whom he encouraged in his investigations on vaccination against rabies, Vulpian himself having performed under the eyes of Pasteur the first vaccination, owing to the fact that Pasteur did not have perfect control of his hand movements. Monday, a visit was paid to the former services of Vulpian, and of Pinel in the Hôpital de la Salpêtrière, and a special meeting of the Société médico-psychologique was held. Tuesday, the Société de neurologie held a formal session, and the Academy of Medicine, in extraordinary assembly, listened to the eulogies of Vulpian and Pinel under the chairmanship of M. Herriot, minister of public instruction. In the evening a banquet was given in honor of the foreign delegates. Wednesday, at the eighth international neurologic convention held at the Hôpital de la Salpêtrière, MM. Lhermitte and Tournay read papers on normal and pathologic sleep. In the afternoon, there was an official reception of the whole assembly at the Hôtel-de-Ville de Paris. Thursday, at a second session of the international neurologic convention, papers were presented by Klejn of Utrecht and Hautant of Paris on the means of clinical exploration of the vestibular apparatus.

Vascular Sympathectomy to Combat Varicose Ulcers

M. Cotte, professor at the Faculté de médecine de Lyon, following the example of Leriche in the use of arterial sympathectomy, applied the method to the femoral artery in two patients with rebellious varicose ulcers. He secured excellent results and rapid spontaneous cicatrization. However, in one case he had first improved the local condition by diathermy and electric treatment, applying at the same time extirpation of the saphenous vein; in the second case he had applied Thiersch skin grafts. While the treatment was admittedly complicated, M. Cotte observed that the results were more rapid and more complete than when sympathectomy was not performed simultaneously. At the meeting of the

Société de chirurgie de Lyon, at which the communication was presented, M. Bérard confirmed in all respects, on the basis of his own personal observations, the conclusions of M. Cotte.

Special Railway Coaches for the Transportation of Invalids

The railway company operating between Paris and Lyons, together with ports on the Mediterranean, is a line that transports every year a large number of patients, for its trains ply to and from the Riviera, which is much frequented by convalescents and the tuberculous. There has been in the past considerable criticism of the railway company in this connection, because of the danger of spreading disease among the other passengers. All the company was able to do was to subject the interior of its coaches to frequent and thorough disinfection. But it has recently constructed a special type of car for the transportation of patients which is a model of convenience. The patient is furnished a room 4.5 meters long by 2 meters wide, with an air space of 22 meters, and with a lavatory and toilet adjoining. The room contains a low, polished brass bedstead, which can be dismounted at the will of the patient. The head of the bed is usually placed against the partition of the lavatory in order to allow circulation on three sides. The bed is supplied with a comfortable mattress and springs, which may be easily disinfected. Opposite the patient's bed is another brass bed, placed transversely and transformable into a couch. The patient may therefore have near him, both day and night, the person who is taking care of him. In the patient's room all projections that might serve as dust catchers are avoided. All the corners are rounded out for a similar reason. The walls, the ceiling and the floor all consist of washable material that can be disinfected after each journey. The rugs and the window curtains are of washable fabrics. In each long side of the room there is a large double door to facilitate the admission of the patient. One of the doors, which opens directly into the corridor, may be blocked, in the presence of a contagious disease, to effect complete isolation. Light enters through large windows projecting outward. It may be dimmed by curtains of washable fabric, or completely shut out by means of blinds. The electric light fixtures, placed in the ceiling, make it possible to illuminate the room brilliantly; to have a soft, dim light, or to make the room completely dark. The patient has, furthermore, a reading lamp at the head of his bed, which makes it possible to shut off the light from the ceiling, if desired. Protection against variations of temperature is secured by the use of cork strips to stop up chinks in the walls and the floor and by double windows. When the two window panes are raised, the layer of air between them prevents the dissipation of heat and the penetration of the cold. The double windows prevent also, in winter, the condensation of frost on the window panes. Immense radiators with smooth walls (a new system) cover the two long sides of the room, under the windows. With this equipment a warm temperature can be maintained within even though the mercury drops to the lowest level. The radiators are supplied with air taken from the outside and filtered through layers of cotton, so that ventilation is accomplished with air from which all dust is removed. The radiators may be used, furthermore, in summer to cool the air, ice-water being forced through them in place of steam. The cork strips in the walls and floor serve likewise to deaden the noise and to absorb the shock. The lavatory adjoining the patient's room contains a toilet seat and flushing tank and a stationary bowel with hot and cold water. In case the patient has an infectious disease, the toilet seat is supplied with an hermetically sealed receptacle in order to prevent contamination of the roadbed or of the trucks with infectious matter. The receptacle is thoroughly disinfected at the end of each journey. The service room is supplied with hot and cold water, an icebox, a water-bath, an electric heater, an electric chafing-dish for the preparation of foods and beverages, a medicine chest, a linen cupboard, a cupboard for dishes, and an air-tight receptacle for soiled linen. The car is provided also with a Rouvillois stretcher for carrying persons severely injured or helpless patients. The stretcher can be sent for the patient, the patient can be transferred to the bed in the railway car, and on reaching his destination can be carried on the litter to his home or hospital.

PRAGUE

(From Our Regular Correspondent)

June 1, 1927.

Venereal Disease

Under the Czechoslovak law concerning venereal diseases, only the cases which occur in patients who have lapsed in treatment or those who have not complied with the orders given to them by the physician must be reported to health authorities. The central health authority may make the reporting of all cases of venereal diseases obligatory for a limited period of time, provided the names of patients are not required. This provision was made in order to make it possible for the health administration to collect information on the prevalence of venereal diseases in the country. The first country-wide reporting was carried out in February, 1921. Because the law relating to venereal diseases was not in force at that time the reporting was optional. Nevertheless its results were good. More than 21,000 venereal cases were reported. The second reporting, along similar lines, was organized in February, 1926, under the provisions of the law. In this instance, reports were requested only of cases which came under treatment for the first time in the course of the month. The results of the second reporting have been published recently and have shown considerable reduction in the incidence of fresh venereal infections in the course of the last few years. The reduction in the incidence of syphilis for both sexes amounts to 50 per cent; of gonorrhea, around 10 per cent; of chancroid, about 70 per cent. Since the second reporting was carried out under the provision of the law, it was more complete than the first one.

The first reporting was carried out when legitimatized prostitution was still in force. In the middle of 1922, legalized prostitution was abolished. If the opponents of abolition had been right in their assumptions by 1926 the deleterious effects of abolition would have shown themselves in the incidence of venereal infections. The high incidence of infection of married women has decreased. This shows that the conditions following the war were responsible for this phenomenon. Infected soldiers who came back from military service carried the infection into their families. Prostitution has decreased but, on the other hand, extramarital relations have come to the forefront. This can be explained by the measures that have been taken against prostitution as a profession, while the greater freedom for women in present-day society has led to the spread of venereal infection among them. While in the first reporting prostitution was the chief source of infection for men, in the second reporting extramarital relations with nonprostitutes occupy the first place.

Death of Janosik

The death of Prof. J. Janosik of the Czech medical faculty of Prague was announced, May 10. Professor Janosik was the founder of the school of Czech anatomists and histologists. His whole career was connected with the development of the Czech medical faculty of Prague. Born in 1856 in Moravia, he obtained his medical education in Prague. Since 1893 he had been chief of the anatomic institute of the Czech medical faculty in Prague. Under his guidance the whole present generation of Czechoslovak physicians was introduced into the study of medicine. He established his reputation through his studies on the development of the genito-urinary organs and of the suprarenal glands. He has also written textbooks of anatomy and histology, respectively, which have become standard reference books for the whole Czechoslovak medical profession.

Masaryk League

The Masaryk League Against Tuberculosis recently reviewed at its annual meeting its activities of last year. While the tuberculosis mortality for 1924 was at the low figure of 190 per hundred thousand, it has increased since that time. Last year's mortality was 196 per hundred thousand. This has occurred in spite of the increased activities of the league. At present the league has local branches in 293 communities, including all the provinces of the country. The chief activities of the local branches were concerned with educational campaigns. Dispensaries exist in 179 places. The whole league has more than 37,000 paying members. The public contributes during the week of the annual spring drive. The organization of regional conferences and public health exhibits has proved effective in spreading interest in the work of the league. A course for physicians and another for public health nurses was organized last year. Special effort was made last year to obtain cooperation between the league and the sickness insurance organizations. In many instances a contract was made according to which members of the insurance organization are to be supervised by the dispensaries. In this way, the campaign against tuberculosis was assured of uniformity of method, a desirable condition which would be endangered if the insurance bodies had organized an independent campaign. The activities of the league have been extended to include protection of children who are exposed to tuberculosis. Summer camps and preventoriums have been established, partly independently and partly in connection with other child welfare agencies. The league had to continue to pay the fees of indigent consumptives in tuberculosis hospitals although this is one of the least productive expenditures. The league has continued its efforts for the formulation of a special law relative to the campaign against tuberculosis. The time for such a law seems to be ripe because it is felt that voluntary support should be supplanted by official activities and optional cooperation by compulsion.

Title of Specialist

The ministry of health recently has been brought before the supreme court by the chamber of physicians of Moravia because the ministry has given to a physician who applied for it the right of using the title of "specialist." Up to the present the usage in this country has been that the title of specialist might be given by the chambers of physicians. These organizations exist as independent autonomous bodies in each of the provinces. The supreme court upheld the ministry of health. As a result, the ministry of health has issued rules and regulations according to which the title of specialist may be granted. Branches of medicine in which the title of specialist can be given are internal diseases, diseases of the heart and the vessels, diseases of the lungs, tuberculosis, diseases of metabolism, neurology, psychiatry, physical therapy, roentgenology, balneology, pediatrics, otorhinolaryngology, ophthalmology, surgery, orthopedics, urology, gynecology, dermatology, venerology and medical laboratory methods. A combination of several of the branches enumerated is allowed only in the instances of allied specialists, for each of which a separate and equivalent qualification shall be required by the authorities. Those who apply for the title of specialist shall produce a certificate showing that the applicant, after his graduation in medicine, has spent at least two years in surgery, gynecology, ophthalmology and internal diseases, and three years in an institution where he has had a chance to acquire a thorough practical knowledge of the branch of medicine in which he wants to specialize. University institutes and departments of large hospitals are considered as institutions offering the necessary facilities for training. Internship only in such institutions can be credited in the set probation period. Courses in the special branch of medicine given in similar institutions should not be longer that one fourth of the probation period. Experience in foreign countries is equivalent to that at home. A person who has obtained the right to use the title of specialist but who has not practiced the specialty for a period of five years loses the right to use the title. Those who wish to practice a medical specialty must announce their desire to the provincial health department, which has the right to examine the documents of applicants and to refuse or accept their qualifications.

Better Housing Week

For the first week of May the Health Week of the German population in Czechoslovakia was organized. The purpose of the campaign was to demonstrate that healthy housing is of capital importance for the prevention of sickness and that much can be done in order to improve housing in spite of the present adverse financial situation. Much could be achieved if the space available in many of the family apartments was used in a rational way. In many families, the best room is set aside for special occasions, such as the visits of friends, while it is not used at all by the family itself. The standards of the American home and the American family house were given wide publicity in lectures presented during the week. An office has been opened in Prague where instruction is given concerning advantageous ways of obtaining the necessary capital for erecting a house and concerning plans for its construction.

BERLIN

(From Our Regular Correspondent)

June 4, 1927.

Meeting of the German Surgical Society

The congress of the Deutsche Gesellschaft für Chirurgie was held in Berlin, April 20-23, 1927, under the chairmanship of Küttner of Breslau. The first main topic on the program was: "Newer Points of View on the Preparation and the After-Treatment of Persons Operated on." Rost of Mannheim gave a survey of the deaths occurring during the past four years in the surgical department of the Mannheimer Krankenhaus. Approximately a third of the deaths were due to infection and injuries, a third to tuberculosis and malignant tumors, and a third to peritonitis, operations on the stomach and gallbladder, etc. Ten per cent of the deaths of the last group were due to heart failure, which shows the need of a more careful estimate of circulatory conditions before an operation is underaken. In the testing of heart function carried out during the last nine months on patients about to be operated on, as reported by Schrumpf, Gönczi, Mosler, Katzenstein and Kauffmann, it was found that more hearts than was commonly supposed were unable to function normally. A diseased heart should be treated with digitalis before the operation. The indiscriminate administration of digitalis to all persons who are to be operated on is, however, reprehensible. The newer heart remedies were discussed briefly; also the importance of camphor in the treatment of pneumonia, of quinine and quinidine in exophthalmic goiter, of epinephrine in sudden heart failure, of strychnine and caffeine to bring about contraction of the vessels, and of amyl nitrite, glyceryl trinitrate and papaverine in high blood pressure was emphasized. For the increase of embolism in recent years, and, more particularly, for the outbreak in November and December, 1926, no definite cause has been discovered. That certain types of persons are predisposed to embolism could not be proved. Against postoperative pneumonia there is as yet no sure prophylactic nor any reliable remedy. The newer remedies (pneumococcus serum, calcium chloride urea, injection of ether or patient's own blood, inhalation of carbon dioxide, roentgen irradiation, etc.) have, however, proved effective in many cases. The changes in the acid-base equilibrium and the composition of the protein bodies after anesthesia and operation must be noted. Acidosis in itself does not work harm, but, just as the disturbances in protein metabolism, is to be taken as evidence that the bodily economy has undergone extensive and far-reaching changes. The recommended infusions of dextrose, with and without insulin, and the ingestion of sodium, do not influence postoperative disturbance of metabolism but are of value in that they protect the liver against deprivation of glycogen. If severe vomiting occurs, sodium chloride must be given owing to the reduction of that element. *Infusions by the drip method* are recommended, following operations. Ringer's solution and normosal are liable to cause chills, so that the author has gone back to physiologic sodium chloride solution. Ingestion of liquids after operation is very important (fever in children due to thirst). Of great importance is the correct preparation of the intestine (not too strong cathartics) and prophylaxis of postoperative paralysis of the intestine (cholin, hypophysin, solution of pituitary). One thing that is much neglected before operations is the preparation of the buccal cavity, although that is a matter of considerable importance. Likewise, the mutual relations between physical and mental conditions must not be neglected (shock, fright psychoses, deliriums, fear and its sequels). The proper furnishing of the sickroom aids the patient just as the correct use of hypnotics and anodynes. Of great importance is also a correct diet for surgical patients, both following the operation and later. In large hospitals, the nurse in charge of the diet kitchen should visit the patient along with the physician and serve as mediator between the desires of the physician, the patient and the management. The creation of a diet kitchen of one's own is also both feasible and advisable. In order that an operation may be successful, good and not too short preparatory treatment, as well as a suitable general after-treatment, as distinct from the special wound treatment, which the speaker did not discuss in detail, is needed.

Concerning postoperative psychoses, which develop in about 0.2 per cent, the male sex predominating, Volkmann of Halle reported that two thirds of the cases recorded in the literature and twelve of his own cases belong to the excitable type, and one third to the melancholic type with thoughts of suicide. Treatment, for the most part, can be only symptomatic. Caution is indicated if psychoses have occurred in the family history or in the patient himself on previous occasions, and when there is great fear of the operation.

Taking up the subject of lung surgery, Sauerbruch of Munich discussed the origin and the surgical treatment of bronchiectasis. Whereas formerly it was the general belief that bronchiectasis developed in association with inflammatory changes in the lungs, the fact that in 80 per cent of the cases the involvement concerns the left lower lobe gives food for thought. Careful researches have shown that inflammatory changes do not ordinarily exist and that everything points to congenital origin. The embryologic development of the lungs shows also that, to the right, nothing opposes lung development, whereas to the left, the heart interposes itself like a wall and that, in some cases, the duct of Cuvier opposes itself as an obstacle to bronchial development. Depending on the time when the constriction takes place, there develop large cysts, bronchiectasis or multiple smaller cyst formation. Pathologic symptoms do not ordinarily appear until an infection develops at the site of these anatomic changes. Relief from the severe suffering to which these chronic patients are exposed can be secured only through a radical operation, resection of the left inferior lobe. The author presented four patients who had been cured in that manner.

Voelcker of Halle spoke on the operative treatment of bronchial asthma, and, more particularly, on the earlier type associated with a rigid thorax. He discussed in detail the position in such cases of the ribs in relation to the spinal column, as plainly shown in the roentgenogram, and presented a cured patient in whom he had resected paravertebrally the first to the tenth ribs.

Haberland of Cologne called attention to remote injuries following section of cervical glands. In experiments on dogs, he demonstrated the reduced performance of the heart following division of the stellate ganglion. Kümmell of Hamburg emphasized, on the other hand, that by his *operation, which is indicated only in the most severe cases,* he effected a cure in 60 per cent of the cases. The unpleasant secondary manifestations have been eliminated since he no longer removes the cervical ganglion but only the stellate ganglion. He welcomes the Voelcker operation, which is indicated in the presence of a rigid thorax, for he admits that it will help to reduce the percentage of failures resulting from his own operation.

SURGERY OF THE PANCREAS

The second main topic on the program was surgery of the pancreas. Schmieden, surgeon of Frankfort-on-the-Main, after a brief historical introduction, in which he made mention of the well known monograph of Körte, described the anatomic picture as it is presented in necrosis, hemorrhage and inflammation, and then took up the subject of pathogenesis. He enumerated the following possible modes of origin: infection (1) from the duct of Wirsung; (2) from the duct of Santorini through the contents of the duodenum; (3) from the common bile duct; (4) through arterial embolism; (5) through retrograde venous circulation; (6) through traumatic insult; (7) through duodenal ulcer (direct transmission to the head of the pancreas); (8) through a duodenal diverticulum in the pancreas. He emphasized the explosive nature of the origin of the disease, which may be precipitated or released by the passing of a small stone past the papilla. Stasis or infection of the pancreas may be brought about by any of the diseases of the biliary system, so that these may be designated as associate diseases. In every operation on the stomach or duodenum there is danger of the pancreas being injured and of a resulting pathologic condition of that organ. The excision of a penetrating ulcer should be avoided, if possible, owing to the danger of injury to the pancreas. But in addition to these well known modes of origin there appears to be an obscure, imperfectly understood factor associated with the development of necrosis of the pancreas, which may be referred to as a pancreas diathesis. Among other causes the speaker mentioned briefly infestation with ascarids, meat and sausage poisoning, and metastatic conditions, especially following proctitis and remote operations. The main danger from acute pancreas conditions consists, first, in hemorrhage from the omental vessels resulting from their digestion; secondly, in fat necroses, which develop, at times, after about sixteen hours, the transmission occurring through the lymph paths or by direct contact, and, thirdly, in peritonitis which follows, together with sepsis. Early operation is the operation of choice. The prognosis as to the course is uncertain and it is therefore impossible to state what the interval of the condition will be. In the event of a severe collapse, and likewise in late cases, if the pulse is strong, one may occasionally wait until an abscess or cyst develops. However, it is not advisable, if there is a suspicion of a pancreas affection and severe abdominal symptoms, to wait until the complete clinical manifestations of the disease have developed. Acting on the principles here laid down, the author succeeded in effecting cures in 48.8 per cent of his cases, which leaves still the very high mortality rate of 51.2 per cent. The object of the operation is to remove the exudate and to reduce the gland to a state of quiescence through incision of the capsule (sometimes incision of the gland itself, with avoidance of the excretory ducts). Often opposing incisions are needed, and the operator must be on the lookout for intraperitoneal and retroperitoneal pus pockets.

Von Bergmann of Berlin emphasized that animal experimentation had increased our knowledge of the nature of pancreas disease, because it has proved possible to produce in animals what we observe in man. The essential thing is the ferment that is formed in the gland. Speaking figuratively, the powder lies in the gland all ready to be touched off, and only a slight happening is required to cause the explosion. The bacterial factor must not be neglected, but it is not a necessary precondition. Autodigestion is a prime factor. The previous ingestion of trypsin preparations has produced sometimes a measure of immunity, but it has not proved possible to establish a passive immunity. Von Bergmann, also, holds the view that in severe acute attacks a cure can be effected only by prompt operative intervention. On inquiring carefully into cases it will be found that occasionally several lighter attacks have preceded the present severe attack. Frequently after attacks of gallbladder disease one hears of pains radiating to the left side. The speaker is of the opinion that such pains indicate involvement of the pancreas. Greater attention should be paid to such disturbances than has been given in the past. Determination of Head's zones is important. Diastase examination of the blood and the urine, and testing of the duodenum (pain attacks following ether) are excellent diagnostic aids. The largest percentage of diseases of the pancreas comes under the head of cholecystopathies (dyskinesia, cholecystitis and cholelithiasis). It does not require a large stone to produce a pathologic condition. As a rule, there is a neuropathic complex, which causes bile and trypsin to be shunted about without the correct entrance into the duodenum being found. Also cholecystectomy may create a predisposition to pancreas disorders that develop later. A long period of postoperative dieting and treatment with trypsin is needed in the above described light attacks, for it is possible that, if the light attacks are treated, the number of severe attacks may be reduced.

(To be continued)

Marriages

Abraham Allen Goldbloom, Pittsburgh, to Miss Ruth Held, of New York, at Berlin, Germany, April 10.

Leo C. Culligan, Rochester, Minn., to Miss Jeane Marie Dennis of Marquette, Mich., June 1.

Holcombe H. Burt, South Boston, Va., to Miss Martha Lee Adams of Blackstone, June 15.

John M. Blades to Miss Anna Mae Sloan, both of Butler, Ky., June 3, at Somerset.

Donnell B. Cobb, Goldsboro, N. C., to Miss Sara Elizabeth Borden, June 4.

Guy Watts Wagner to Miss Blanche E. Thomas, both of Chicago, June 4.

Henry Goodfriend, Boise, Idaho, to Miss Rosa Marks, June 5.

Deaths

William Sweeny Stucky ⊕ Lexington, Ky.; University of Michigan Medical School, Ann Arbor, 1908; member of the American Academy of Ophthalmology and Oto-Laryngology; president of the Fayette County Medical Society; on the staffs of the Good Samaritan Hospital and the Odd Fellows Orphans' Home; aged 43; died, June 10, of cerebral hemorrhage.

Edward Arthur Bowles ⊕ Hebron, Neb.; Detroit Homeopathic College, 1903; Medical Department University of Illinois, Chicago, 1905; past president of the Thayer County Medical Society; part owner and surgeon of the Blue Valley Hospital; county physician; aged 47; died suddenly, June 3, at a hospital in Omaha, of chronic valvular heart disease.

Clarence Couch Elebash, Selma, Ala.; Medical Department of the Tulane University of Louisiana, New Orleans, 1909; member of the Medical Association of the State of Alabama; served during the World War; on the staff of the Vaughan Memorial Hospital; aged 38; died, June 2, at Asheville, N. C., of pulmonary tuberculosis.

Albert Pearson Woodward, San Francisco; Bellevue Hospital Medical College, New York, 1886; for many years professor of dermatology, College of Physicians and Surgeons of San Francisco; formerly on the staff of the Hospital for Children; aged 72; died, May 16, at Stockton, Calif., of cerebral arteriosclerosis.

Joseph R. Mountain ⊕ Connersville, Ind.; University of Michigan Medical School, Ann Arbor, 1898; past president of the Fayette County Medical Society; on the staff of the Fayette Memorial Hospital; aged 55; died, June 10, at the Clinic Hospital, Cleveland, following an operation for abscess of the liver.

Robert Madison Slaughter, Washington, D. C.; College of Physicians and Surgeons, Baltimore, 1879; member of the Medical Society of Virginia; formerly member of the state board of medical examiners of Virginia; aged 70; died, June 3, at a sanatorium in Silver Spring, Md.

Frank Maxwell McCartney ⊕ Denver; Gross Medical College, Denver, 1902; on the staff of the Denver General Hospital and for ten years chief of staff of St. Anthony's Hospital; aged 52; died, June 5, of septic pneumonia and erysipelas of the face.

Mary Miller Battels, Ashtabula, Ohio; Universiy of Michigan Medical School, Ann Arbor, 1888; member of the Ohio State Medical Association; aged 66; died, June 9, at the Ashtabula General Hospital, of injuries received in an automobile acicdent.

George Allen Lightle, Ashland, Ill.; College of Physicians and Surgeons, Keokuk, 1896; member of the Illinois State Medical Society; aged 57; died, June 6, at St. John's Hospital, Springfield, of intestinal obstruction following a cholecystectomy.

George Rescarick Moore ⊕ Trenton, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1897; for twenty-eight years on the staff of the Mercer Hospital, where he died, June 6, following an operation for acute appendicitis, aged 56.

Robert A. Cushman, Princeton, Ind.; Medical College of Indiana, Indianapolis, 1902; member of the Indiana State Medical Association; formerly mayor of Princeton; aged 51; died, June 7, at the Walker Hospital, Evansville, of uremia.

Nathan Lytle Clarke ⊕ Meridian, Miss.; Louisville (Ky.) Medical College, 1883; formerly professor of theory and practice of medicine, Mississippi Medical College, Meridian; aged 70; died, May 17, of hemorrhage, due to gastric ulcer.

Albert Theodore Kaupp ⊕ Wenatchee, Wash.; Jefferson Medical College of Philadelphia, 1891; on the staffs of the Central Washington Deaconess Hospital and St. Anthony's Hospital; aged 63; died, May 28, of chronic poliomyelitis.

Marcus Denis Cronin ⊕ Albany, N. Y.; Albany Medical College, 1907; formerly instructor in surgery at his alma mater; on the staff of St. Peter's Hospital; aged 47; died, May 29, of chronic myocarditis and pulmonary edema.

Jeremiah Francis Calef ⊕ Middletown, Conn.; Yale University School of Medicine, New Haven, 1880; past president of the Connecticut Medical Examining Board; on the staff of the Middlesex Hospital; aged 71; died, June 8.

John Shackford Grouard ⊕ Nantucket, Mass.; Harvard University Medical School, Boston, 1889; on the staff of the

Nantucket Cottage Hospital; aged 60, died, May 31, in Boston, following an operation on the gallbladder

Lewis Byron Dawley, Westtown, N Y, Eclectic Medical Institute, Cincinnati, 1880, member of the Medical Society of the State of New York; aged 65, died, June 2, at the Roosevelt Hospital, New York, of splenomegalia

George Wootson Lacy, Kirkmansville, Ky, University of Louisville School of Medicine, 1909, member of the Kentucky State Medical Association, aged 43, died, in June, at a hospital in Louisville, following a long illness

Arthur Thomas Pritchard ⊕ Asheville, N C, Jefferson Medical College of Philadelphia, 1905, served during the World War, on the staff of the French Broad Hospital, aged 45, died, May 26, of heart disease

John Paxton Tillery, Knoxville, Tenn; University of Tennessee College of Medicine, Memphis, 1889, member of the Tennessee State Medical Association, aged 63, died suddenly, May 29, of heart disease

Robert T. Glassell, Bowling Green, Va, University of Maryland School of Medicine, Baltimore, 1886, member of the Medical Society of Virginia, aged 72, died, June 4, of carcinoma of the parotid gland

William Routt Cravens ⊕ Bloomfield, Ind, Kentucky School of Medicine, Louisville, 1892, Central College of Physicians and Surgeons, Indianapolis, 1896, aged 58, died, June 4, of cerebral hemorrhage

Isaac S. Bowers, Perrysburg, Ohio, Detroit Medical College, 1881, member of the Ohio State Medical Association, part owner of a hospital bearing his name, aged 70, died June 3, of heart disease

Samuel Van Kirk Kennedy ⊕ Warren, Ohio, Ohio Medical University, Columbus, 1905, on the staffs of the Warren City, and St Joseph's Riverside hospitals, aged 45, died, May 28, of pulmonary tuberculosis

James Pervine Atwood, Baker, Ore, Willamette University Medical Department, Salem, 1870, College of Physicians and Surgeons, New York, 1874, aged 81, died, June 15, of cerebral hemorrhage

Lamar Matthew Power, Detroit, College of Physicians and Surgeons, Chicago, 1903, aged 48, died, June 5, at the Providence Hospital, of injuries received when he fell from a second story window

Marion MacMillan Kershaw, Augusta, Ga, Medical College of the State of South Carolina, 1903, member of the Medical Association of Georgia, aged 50, died, June 1, of tuberculosis of the hip

George F. Kelly ⊕ Milwaukee, Chicago College of Medicine and Surgery, 1915, formerly on the staff of the Marquette University Hospital, aged 45, died, May 30, at a hospital in Wauwatosa

Michael Edward O'Donovan ⊕ New York, Medical Department of Columbia College, New York, 1891, aged 70 died in June, of spinal osteoarthritis, acute myelitis and carcinoma of the right lung

Edward L. Mitchell ⊕ Monmouth, Ill, Rush Medical College, Chicago, 1882, aged 71, died, June 9, at Augustana Hospital, Chicago, following an operation for intestinal obstruction

Louis Desire Onesiphore Jacques, Worcester, Mass Laval University Faculty of Medicine, Quebec, Que, Canada, 1895, on the staff of the Louis Pasteur Hospital, aged 54, died, May 30

John Wesley Anderson, Odon, Ind, Kentucky School of Medicine, Louisville, 1881, member of the Indiana State Medical Association, aged 72, died suddenly, June 3, of heart disease

Henry S Llewellyn, La Grange Ill, Hahnemann Medical College and Hospital, Chicago, 1892, Chicago Homeopathic College, 1893, aged 68, died suddenly, June 21, of heart disease

Lewis Duncan Mason, Brooklyn, Long Island College Hospital, Brooklyn, 1886, member of the Medical Society of the State of New York, aged 84, died, June 11, of edema of the lungs

George Johnson Boyd ⊕ Beaver Falls, Pa, University of Michigan Medical School, Ann Arbor, 1889, on the staff of the Providence Hospital, aged 66, died, May 29, of parotitis

William Adrian Thomas, Detroit, *Ohio* State University College of Medicine, Columbus, 1925, aged 29 died April 30, at the Delray Industrial Hospital, of acute endocarditis

William Seitz, Portsmouth, Ohio, Eclectic Medical Institute, Cincinnati, 1908, aged 48, died, in June, at a hospital in Cincinnati, of hiccup following an operation

Robert Kains, St Thomas Ont, Canada, Trinity Medical College, Toronto, 1872, M R C S, England, 1875, for ten years county jail surgeon, aged 78, died, May 3

Oscar Turner Harris, Grayson Ga, Georgia College of Eclectic Medicine and Surgery, Atlanta, 1901, aged 52, died, May 28, at Clarkston, of cerebral hemorrhage

Norman Call, Brookline Mass, Medical Department of Columbia College, New York, 1872 aged 82, died in May, at the home of his niece in Brunswick, Maine

Louis E Alderman, Brooklyn, Eclectic Medical College of the City of New York 1895, aged 56, died in April, of skull fracture received in an automobile accident

Joseph Beisman ⊕ Detroit, St Louis Medical College, 1890 aged 63 died, May 31 at the Highland Park (Mich) General Hospital, of cerebral hemorrhage

Charles Theophilus Maas, New Brunswick, N J, Medical Department of the University of the City of New York, 1886, aged 75, died, June 2 of hemiplegia

Charles Dwight Freeman ⊕ Medina, Ohio, Bellevue Hospital Medical College 1884 aged 74, died, April 22, at the Lodi (Ohio) Hospital, of arteriosclerosis

Richard Rutt Hopkins, Toronto, Ont, Canada, Trinity Medical College Toronto 1887, on the staff of the Grace Hospital, aged 72 died suddenly, May 5

Noah E. Brumbaugh, Seven Mile, Ohio Eclectic Medical Institute, Cincinnati, 1859 Civil War veteran, aged 94, died, May 23, as the result of a fall

William Ulysses McKenzie, Centerpoint Tenn, Vanderbilt University School of Medicine, Nashville, 1877, aged 72, died, April 2 of heart disease

Robert Hudson Crabb ⊕ Leonard Texas, University of Tennessee College of Medicine, Memphis, 1892 aged 67, died, June 5, of heart disease

Clarence Edwin Vaughan, Athol, Mass (licensed Massachusetts, 1924) aged 30, died, June 11, of injuries received in an automobile accident

William A. Halbert ⊕ Springfield, Ill, College of Physicians and Surgeons Keokuk 1882, aged 66 died May 30 at St John's Hospital

Thomas H. O'Rourke, Detroit Detroit College of Medicine and Surgery, 1896, aged 64, died May 21, of pneumonia, following influenza

Magnus Wilkie Kyde, Helena Mont, Rush Medical College, Chicago 1921, aged 31, died, June 7 of potassium cyanide poisoning

Robert Howell Preston Wright, Junction, Texas (registered, Texas, under the Act of 1907), aged 55, died, June 9, of acute myocarditis

Nathan W Melton, Wayne City, Ill, American Medical College, St Louis, 1883 aged 85, died, June 17, of cerebral hemorrhage

Jacques Daniel de Chantreau ⊕ San Francisco, University of Paris France, 1891, aged 61, died June 10, of chronic myocarditis

Jacob Oren Malsbury, Peru, Ind, Kentucky School of Medicine, Louisville, 1890, aged 62, died, May 21, following a long illness

Helena M Mullhaupt, St Marys, Pa, Woman's Medical College of Pennsylvania, 1880 aged 67, died, May 26, of pneumonia

John C Taylor, Canton, Ky, University of Tennessee College of Medicine, Memphis, 1889, aged 59, died, May 30, of nephritis

Daniel Lyons, Ashland, Ill, American Medical College, St Louis, 1883, aged 79, died, May 26, of carcinoma of the nose

Robert P. R Huyett, Shillington, Pa, Jefferson Medical College of Philadelphia, 1878, aged 71, died, May 3

Harry William Purdy, Nogales, Ariz Bellevue Hospital Medical College, New York, 1882, died, March 24

Abner A. Alford, Newhope, Ark, Fort Worth (Texas) School of Medicine, 1904, aged 72, died, May 14

E D Ehrman, Rockport, Ind (licensed, Indiana, 1897), aged 73, died, June 8, of cirrhosis of the liver

Adolph Hans Olsen, Oak Park, Ill (licensed, Illinois, 1898), aged 57, died, May 15

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

TWO OBESITY FAKES DODGE FRAUD ORDERS

Hall's Tablet Triturates.—The Hall Chemical Company of St. Louis has for many years sold a fake cure for obesity, which it called "Hall's Tablets Triturates." As is common in the nostrum business, the composition of the preparation has varied. When analyzed in 1920, the product was found to be essentially a mixture of ginger, nux vomica, aloes and chalk. In 1926, the essential active ingredients of the Hall preparation were aloes, ginger and phenolphthalein.

Three ways to reduce your weight

Particulars mailed free to any address.
Hall Chem.Co.Dept. B-119 St. Louis, Mo.

Jan. 24, 1927, the Post Office Department called on the Hall Chemical Company to show cause why a fraud order should not be issued against it, and gave the concern a month to prepare its case. In about two weeks' time A. N. Gaebler, proprietor of the Hall Chemical Company, submitted an affidavit to the Post Office Department declaring that the sale through the mails of Hall's Tablets Triturates had been absolutely discontinued and abandoned, and would not be resumed under that name, or any other name. He declared, further, that he had directed the Postmaster at St. Louis to return to the writers all mail hereafter received, addressed to the Hall Chemical Company, with the legend "Out of Business" stamped or written on the envelop.

Slends Chewing Gum.—Readers of this department of The Journal may remember that in the issue of Nov. 13, 1926, under the title "More Fat Cure Fakery," there was an article dealing with two quack "obesity cures" of the chewing gum type. One of these was "Slends," put on the market by Slends, Inc., and by the Heath Products, Inc. Slends was analyzed in the A. M. A. Chemical Laboratory and was reported to be essentially chewing gum (chicle), coated with varying amounts of a mixture containing sugar and phenolphthalein, flavored, and containing a small amount of vegetable extractives.

Slends

Avoid Excess Fat

Sept. 14, 1916, the Post Office Department called on Slends, Inc., the Heath Products, Inc., and E. M. Heath, president, and C. L. Heath, secretary and treasurer, to show cause why a fraud order should not be issued against them for selling Slends through the mail, under representations that were alleged to be false and fraudulent. Jan. 3, 1927, Ernest M. Heath and C. L. Heath submitted an affidavit to the Post Office Department declaring that the business of selling Slends through the mails had been entirely discontinued and abandoned, and would not be resumed under that name or any other name, and that neither of these men would hereafter engage in the sale of any fat-reducing preparation through the mails.

There is, of course, nothing in the action of either the Hall Chemical Company or Slends, Inc., to prevent either, or both, of these concerns continuing to sell their products through the drug stores. This course of action has been taken before by quacks who have signed similar affidavits in order to avoid the unpleasant consequences of the issuance of fraud orders.

CACTINA PILLETS AGAIN

Twenty years ago preparations of *Cactus grandiflorus*—the Mexican night-blooming cereus—had considerable vogue, chiefly because of the extravagant advertising claims made for two preparations said to be derived from it—"Cactin" and "Cactina." Sollmann, in one of the chapters of his "Broader Aims of the Council on Pharmacy and Chemistry" (The Journal, July 4, 1908, p. 52) thus ironically describes the claims made for these preparations:

> "Should the heart be too slow, cactus quickens it; if the heart is too fast, cactus slows it; should the heart be too weak, cactus strengthens it; if the heart is too strong, cactus weakens it; does the heart wobble, cactus steadies it; if the heart is normal, cactus does not meddle with it."

In 1907, R. A. Hatcher discussed the conflicting evidence of those who had reported on the composition and action of *Cactus grandiflorus,* stating that he had been unable to find a single conclusive piece of pharmacologic work showing that the drug possesses any physiologic action whatever, and that, on the other hand, the work of Houghton pointed to its entire uselessness and that of Gordon Sharp showed it to be wholly inert (The Journal, Sept. 21, 1907, p. 1021).

In 1908, S. A. Matthews reported that when administered to a dog intravenously large doses of cactina cause a slight fall in blood pressure and depress both the respiration and circulation. He reported, further, that from experiments on guinea-pigs, rabbits and himself, cactin in one thousand times the recommended dose is physiologically inert (The Journal, March 21, 1908, p. 956; April 4, 1908, p. 1140).

In 1910, the Council on Pharmacy and Chemistry reviewed the evidence for the value of *Cactus grandiflorus* and concluded that there was no evidence to make any available preparation a reliable remedy (The Journal, March 12, 1910, p. 888). In 1910, also, E. P. Lyons and C. L. Quall made a large number of experiments with cactina on animals, on healthy men and on patients in bed, and were unable to demonstrate any effect on the heart beat or the circulation (The Journal, Aug. 6, 1910, p. 455).

Because previous work had been questioned on the ground that it did not deal with Mexican night-blooming cereus, Hatcher and Bailey in 1911 procured authentic specimens of the true Mexican variety and, using their own preparation as well as representative preparations bought in the open market, in a series of experiments on cats, dogs and frogs, conclusively showed the drug to be inert, obtaining no perceptible effect even from the administration of most colossal doses by mouth to the animals (The Journal, Jan. 7, 1911, p. 26).

As a result of the thorough exposure of the worthlessness of cactus preparations, proprietary houses have generally abandoned their exploitation. While "Cactin" (now called "Cactoid") is still offered for sale and is still the "joker" in a proprietary morphine-scopolamine preparation, no claims for it are advanced. In the case of "Cactina Pillets", however, the proprietor—the Sultan Drug Co.—still finds it profitable to continue advertising in a certain class of so-called medical journals and to continue making the claims that have been so thoroughly disproved.

It is to be presumed that those who use Cactina Pillets do so because they have accepted the claims contained in the advertising at their face value, have done this without informing themselves of the published evidence, and have used this worthless preparation without adequately controlling the expected effects on their patients. To these, a report by Dr. Clifton B. Leech from the Cardiac Department of the Union Hospital in Fall River will be of interest (*Boston M. & S. J.*, March 10, 1927, p. 394). Dr. Leech first tried the drug in doses of from one to 300 pillets on groups of healthy persons including himself, and observed no effects. He then tested the pillets in patients presenting the signs and symptoms for which cactina is recommended—ten patients with extrasystoles, four patients with constrictive pain in the precordium, ten patients with paroxysmal, constrictive, substernal pain, five patients with effort syndrome, four patients with neurocirculatory disturbances, ten patients with myocardial weakness, and two patients with auricular fibrillation and marked congestive failure. In no case did he observe any beneficial or otherwise distinctive effect from the drug, and he concluded that Cactina Pillets are no more than a placebo, thus agreeing with Sollmann, who twenty years ago called the preparation a psychic cardiac tonic.

It is a sorry commentary on the intelligence of some members of the medical profession that it is necessary to do clinical and experimental work to prove that the moon is not and never was composed of green cheese. But it seems necessary.

Correspondence

GRADUATE TEACHING IN DERMATOLOGY

To the Editor:—Dr. Louis B. Wilson has performed a valuable service in his recent painstaking review of graduate medical education in Europe (The Journal, June 11). In his brief reference to dermatology in America, however, he has made some misstatements which show his unfamiliarity with the situation in this country.

"It is difficult to explain," Dr. Wilson writes, "why dermatology has been so slow in developing in America." With such a statement I must take issue, feeling that dermatology has developed as fast as other specialties, while in recent years it has made notable strides.

He is evidently not aware of the fact that the oldest dermatologic society in the world is the New York Dermatological Society, founded in 1869; also that the American Dermatological Association, founded in 1876, is the fifth in age of the sixteen component bodies of the Congress of American Physicians and Surgeons. Dr. Wilson might have been surprised to see three hundred or more at the opening meeting of the Section on Dermatology and Syphilology at the recent Washington session. He might be interested to know that at the recent annual meeting of the New York State Medical Society the newly organized Section on Dermatology and Syphilology had a larger attendance than any of the other special branches of medicine. Does he know of the flourishing condition of the section at the New York Academy of Medicine, where the attendance has been so overwhelming that it had to be limited by cards of invitation? Does he know of our most successful international congress of dermatology held in the country twenty years ago? Does Dr. Wilson know of the high regard in which the *Archives of Dermatology and Syphilology* is held by our European colleagues and that our official journal under various names has been published since 1870?

Dr. Wilson's statement that our imagined lack of progress "used to be thought" due to lack of material is hardly accurate. Whatever our shortcomings may have been, they were at least never due to lack of clinic material, which has always been most abundant.

The statement that "many of the larger cities in the United States are without competent dermatologists" is absolutely incorrect at the present time, as there are few cities of a hundred thousand or more without the services of a well trained physician in this branch of medicine.

Finally, I must take most emphatic issue with the statement that "very few places in the United States provide the graduate students with the opportunity of studying more than the mere rudiments of the specialty." At the present time thorough graduate instruction in dermatology-syphilology is given in a number of institutions scattered over the country. Such a list, comprising a dozen medical schools approved by the Council on Medical Education and Hospitals, has been published in The Journal. In New York City alone, graduate instrucation is given in three undergraduate colleges, two postgraduate institutions and one special hospital. It may be of interest to know that the first branch of medicine to be taught to graduates on an ambitious scale in Columbia University was dermatology. The great success achieved by this work under the late Dr. John A. Fordyce was followed by similar activities in other branches of medicine at Columbia. At the New York University and the Post-Graduate Hospital, complete courses of graduate instruction are now given in dermatology-syphilology, including clinical dermatology, histopathology, mycology, roentgen-ray and other forms of physical therapy, and photography. Similar instruction is given in both the graduate and the undergraduate departments at the University of Pennsylvania. One of the most successful schools for graduate teaching is that of the University of Michigan, where a most thorough graduate training is given during a residence of four years.

It is no longer necessary to go abroad for graduate instruction in this specialty. In fact, there are eminent teachers conducting graduate courses who themselves received all their training in this country. We are proud of the advances of recent years in this specialty, one of which is graduate instruction.

Howard Fox, M.D., New York.

THE COUNCIL ON PHYSICAL THERAPY

To the Editor:—At the last day's session of the Section on Orthopedic Surgery, during the recent Washington session, Dr. A. H. Freiberg of Cincinnati read a paper on the relationship of physical therapy to orthopedic surgery. It contained excellent points and was discussed by a number of men, all of whom agreed with Dr. Freiberg that heavy responsibility rests on orthopedic surgeons to set physical therapy straight. None of these men made the slightest reference to the Council on Physical Therapy, which is trying to solve the problem in a broad manner and to establish a proper relationship of physical therapy and the general profession. In contrast to the opinions voiced by some orthopedic men that a class of lay "physical therapeutists" be developed, working under their direction, the Council on Physical Therapy advocates that physical therapy be administered, or at least prescribed, by medical men especially trained in this field.

Dr. Joseph F. Smith of Wisconsin, whose resolution before the House of Delegates at the Atlantic City session in 1925 was responsible for the creation of the Council on Physical Therapy, happened to be present at the orthopedic session and, in subsequent conversation, shared with me his amazement at the fact that in spite of a number of excellent reports by and about the Council on Physical Therapy published in The Journal, its existence should still seem unknown to a whole section of the American Medical Association.

May it not be appropriate to call attention to the work of the Council? It endeavors earnestly to sift the chaff from the wheat in physical therapy and place it within the reach of the entire profession for the best interests of their patients, and should command the fullest cooperation of every broad minded physician.

Richard Kovacs, M.D., New York.

DIAPHRAGMATIC PLEURISY ARACHNIDISM

To the Editor:—I have received from Dr. Emil Bogen an interesting reprint and copy of a letter to you relative to a case reported by me (The Journal, April 30, p. 1395) as one of bilateral diaphragmatic pleurisy simulating perforated gastric ulcer. Dr. Bogen suggests that it was a case of arachnidism. Such a diagnosis was considered before operation and the history of spider bite included as relevant. The day following operation, however, the appearance was that of a respiratory infection, with leukocytosis of 19,000; and this appearance became more marked as the respirations rose from 30 to 48 per minute. The later occurrence and persistence of definite, clear and unmistakable dry pleural friction rubs anteriorly, posteriorly and in the axilla on both sides at the level of the diaphragm just about indisputably establish a diagnosis of bilateral diaphragmatic pleurisy. To suppose an arachnidism also would necessitate the supposition that the pleurisy developed soon after the arachnidism and without producing any noticeable change in the picture—a view that appears to me unlikely. This belief has been strengthened by learning of a series of similar cases occurring in Philadelphia hospitals a few years ago, in several of which operations were performed only to have a final diagnosis of bilateral diaphragmatic pleurisy made.

George L. Carrington, M.D., Durham, N. C.

Queries and Minor Notes

Aonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SUICIDE IN CALIFORNIA

To the Editor:—What explanation can you give, if any, for the comparatively high suicide rate of cities located in California?

H. A. D., Buffalo.

Answer.—This inquiry was referred to Mr. L. E. Ross, Director and State Registrar, Bureau of Vital Statistics, California State Board of Health, who replies in part as follows:

"There has as yet been no satisfactory explanation of the fact that our suicide rate is about double that of the country as a whole. People are killing themselves more than twice as fast as in other states. It is not the natives who are doing it. One fourth of the people living in this state are natives; but only one seventh of the suicides are among natives. 'Normal' is about fifteen suicides per year in every hundred thousand adult population; but the rate in California is thirty-two. During the last three years no less than 2,600 people have killed themselves in this state." (This is from a survey made several years ago.) "The rate for natives was 15; for persons born in other states and living in California the rate was 24; and for the foreign-born it was 35.

"Some of the common causes for suicide are financial reverses, disappointment in love, ill health, impending disgrace, unemployment, fear and insanity. Data are not available to show the proportion of lives claimed by each of these causes, but in looking about for an explanation of our excessive suicide rate, we are inclined to attribute a heavy proportion to ill health. Large numbers of health seekers, especially among the tuberculous, have migrated to California, many of them arriving practically without funds, expecting to secure light employment to defray expenses. There is real tragedy in such cases. A substantial proportion of our high suicide rate can safely be assigned to this group, many of whom destroy themselves when they find that a salubrious climate will not do for them what medical science has failed to accomplish. Financial difficulties are no doubt worse among the males than the females, a larger proportion of men than women coming without funds sufficient for their support, which accounts partly for the excess suicide rate among the males in this state.

"Unemployment can scarcely be assigned any portion of the excess rate, except for the class just mentioned. However, the competition resulting from an excess labor supply is evidenced in the suicide rates for the different age groups. These conditions do not affect Californians any more than people in other states, and do not unduly contribute to our high suicide rate.

"The other causes, such as financial reverses, disappointment in love, and insanity, are no more common in one place than in another, and thus practically everything but ill health is eliminated. Is this alone sufficient to account for all the excess in the California suicides? It may be, but such is not believed to be the case. There are probably other reasons which cannot be discovered through analysis of the vital statistics."

TETANUS ANTITOXIN AND RABIES

To the Editor:—I have recently noticed that many practitioners and some hospitals, both homeopathic and allopathic, are using tetanus antitoxin in the prophylactic treatment of rabies. Is there any sound basis for this from either the theoretical or practical aspects?

Andrew J. L. Guay, M.D., Philadelphia.

Answer.—Tetanus antitoxin is without any effect in preventing rabies. There is no practical or theoretical basis for concluding that tetanus antitoxin can have any direct effect on rabies. The only conceivable reason for using tetanus antitoxin in persons bitten by animals suspected of being rabid would be to guard against the possibility of infection with the tetanus germ at the same time; but this would seem to be a rather remote possibility.

PRURITUS AFTER SULPHARSPHENAMINE

To the Editor:—I have a patient who, one week following the last treatment of a course of sulpharsphenamine, developed a general pruritus, which is very unpleasant. What can I do to relieve him? Please omit name.

M.D., Illinois.

Answer.—When a general pruritus develops from any of the arsphenamines it is a danger signal and any further use of arsphenamine should be cautious. Antipruritic applications may be comforting, such as starch baths, containing 2 liters of boiled starch to the bath. Or the patient may be sponged with calamine lotion, consisting of zinc oxide and calamine, each 30 Gm.; glycerin, 15 cc.; water, to make 500 cc. Or sponge with a liniment, such as olive oil, 200 cc.; lime water to make 500 cc. But the only way to stop the condition is to stop the arsphenamine, and the pruritus is a signal to stop the arsphenamine if it can be done.

PHOSPHATURIA

To the Editor:—What is the cause and treatment of a persistent phosphaturia that has existed for more than six months without signs or symptoms, other than a urinalysis, of its existence? Physical examination does not reveal anything, even focal infection. The patient is apparently a well, normal individual, and came to me on account of noting the whitish color of the urine while voiding. The patient is of normal weight, works every day, and does not complain of any trouble whatever. Repeated attempts to acidify the urine by different chemical agents, including sodium acid phosphate, have proved futile. The urine is absolutely loaded with the earthy phosphates and is precipitated when voided. There is no cystitis.

W. I. Stockdon, M.D., Glendon, N. C.

Answer.—Phosphaturia cannot as yet be called a clinical entity, and opinion regarding its causation and treatment shows considerable diversity. Efforts should, of course, be directed toward lessening the conditions that favor the precipitation. An acidic diet with meat, bread and fat predominating, and vegetables and fruits suppressed, might help in acidifidation of the urine. The administration of calcium, in the form of carbonate, from 1 to 2 Gm. three times a day, has been recommended by von Noorden as lessening the elimination of phosphate in the urine by holding it in the bowel. Tobler believes that there is an excess of calcium in the system, because of endocrine disturbance, and that the disproportion in elimination of calcium to phosphate leads to production of the insoluble form. He advises a calcium-poor diet consisting, in addition to the diet mentioned, of rice, potatoes and sugar, with avoidance of milk, eggs and leguminous products. Excepting that it might lead to formation of a phosphate stone, the condition is really of no consequence and hardly deserves much attention.

EPINEPHRINE WITH HYPOPHOSPHITES

To the Editor:—What is the proper value of the use of the solution of epinephrine hydrochloride when given by mouth and, if of any value, could it be combined for instance with a solution of hypophosphites as a reconstructive after any wasting diseases such as typhoid or influenza? Please omit name.

M.D., South Dakota.

ANSWER.—Epinephrine given by mouth has practically no effect, unless relatively large doses are given (from 0.002 to 0.005 Gm.) in gelatin capsules on an empty stomach. Then a transient rise of blood pressure may be produced; this effect is, however, not constant, and is liable to be accompanied by epigastric and substernal pain and nausea, especially in the presence of hyperthyroidism. It is probably without value as a "tonic" or "reconstructive." The lack of value of the hypophosphites as tonics and reconstructives has been demonstrated most thoroughly ("The Hypophosphite Fallacy," Report of the Council on Pharmacy and Chemistry, THE JOURNAL, Sept. 2, 1916, p. 760).

CALIBRATION OF MERCURY SPHYGMOMANOMETER

To the Editor:—1. Is it true that accuracy requires that each mercury sphygmomanometer be carefully hand calibrated? 2. Is it not a fact that the unit of pressure in blood pressure measurement is the hydrostatic pressure exerted by a column of mercury 1 mm. high, and that, therefore, the scale should be a true millimeter scale; that is, the distance between the 0 and the 300 millimeter graduations, for example, should actually measure 30 cm.? 3. Does accuracy demand that the lumen of the mercury tube be bored with the utmost precision to prevent any variation in its diameter? 4. Is it not a fact that even great variations in the diameter of the lumen of the mercury tube (so long as there is no constriction great enough to prevent the flow of mercury) will make no difference in the accuracy of reading? 5. In other words, how can there be any difference between the hydrostatic pressure exerted by a 200 mm. column of mercury in an irregular tube and that exerted by 200 mm. of mercury in a tube so bored that the lumen is entirely uniform throughout its length?

DEXTER H. WITTE, M.D., Milwaukee.

ANSWER.—1. Yes.

2. By a pressure of 1 mm. of mercury is meant the hydrostatic pressure exerted by a column of mercury 1 mm. high, and consequently a pressure of 100 mm. of mercury is the hydrostatic pressure exerted by a column of mercury 100 mm. high, etc. Then when a pressure of 100 mm. of mercury is applied to the manometer, the vertical distance between the levels of the mercury in the reservoir and in the tube measures 100 mm., but the distance from the zero graduation on the scale to the mercury level in the tube is less than 100 mm., since the scale is fixed and does not follow the changes in mercury level in the reservoir which accompany changes in the applied air pressure.

3. No, if the instrument is calibrated.

4. The magnitude of the variations in bore makes no difference in the accuracy if the instrument is calibrated. Of course, under certain conditions, such as a bore as small as 1 mm. and very dirty mercury, the column might stick and air pockets form.

5. There is no difference.

In the following explanation, a manometer with a reservoir of uniform, circular cross-section is assumed. This simplifies the discussion by requiring consideration only of variations in the glass tube, and does not invalidate the argument at all. The scale is assumed to be fixed permanently with its zero graduation at the zero level of the mercury in the tube and in the reservoir.

In figure 1 is shown diagramatically an ideal manometer having a tube of uniform circular cross-section. Such a tube cannot be obtained commercially, but instead, the commercial tubes vary in bore as indicated in an exaggerated manner in the manometer shown in figure 2.

The position of the scale graduations can be determined for the ideal manometer of figure 1 as follows: If initially no differential pressure is applied to this manometer, the level in the reservoir is the same as the level in the tube, which level is designated as the zero level of the manometer. Suppose that a differential pressure of 20 mm. of mercury be applied to this manometer. The mercury level in the reservoir will fall and the level in the tube will rise until the vertical distance between them measures 20 mm. The 20 mm. graduation of the scale is marked at the point to which the mercury has risen. Similarly all the other scale graduations can be determined.

However, for this ideal manometer, having both tube and reservoir of perfectly uniform bore, the height to which the mercury would rise in the tube for any given pressure could have been computed, provided the ratio of the cross-sectional areas of the reservoir and tube were known. Assume for the sake of argument that the cross-sectional area of the reservoir is nineteen times as great as the cross-sectional area of the tube. Since the volume of mercury which flows out of the reservoir as the level falls from the zero level to the level *AA* equals the volume which is required to fill the tube from the 0 graduation to the 20 mm. graduation, the rise in the tube and the fall in the reservoir must be in the inverse ratio of their cross-sectional areas. Hence the rise in the tube is $\frac{19}{19+1} \times 20 = 19$ mm. and the fall in the reservoir is $20 - 19 = 1$ mm. Also, since the scale remains fixed, the distance from the 0 to the 20 mm. graduation measures 19 mm. Similarly, the positions of any or all the graduations on the scale can be computed and they will be found to be equally spaced by an amount $^{19}/_{20}$ as great as the corresponding number of millimeters pressure.

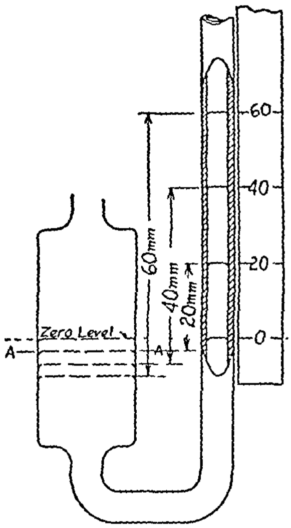

Fig. 1.—Ideal manometer.

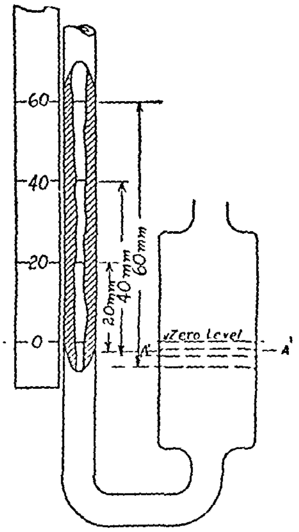

Fig. 2.—Commercial manometer.

This shows that if the tubes and reservoirs of the manometers were perfect, it would not be necessary to calibrate the scales individually.

In the actual manometers, however, it is necessary to calibrate the scale individually owing to irregularities in the bore of the tube. Consider what will happen if the procedure just described is followed with the manometer shown in figure 2, in which the reservoir is circular and of the same diameter at all cross-sections, but in which the bore of the tube varies as shown in a somewhat exaggerated fashion. Initially, for zero differential pressure, the mercury stands at the same level in the tube and reservoir and the zero of the scale is also set to this level. Now apply a pressure of 20 mm. of mercury to the manometer, as before.

The mercury falls in the reservoir from the zero level to the level *A'A'* and rises in the tube until the difference in the two levels is exactly 20 mm. The amounts which the mercury will fall in the reservoir and rise in the tube cannot be computed for this manometer, since we do not know how the bore of the tube varies. Consequently, the only way in which the 20 mm. graduation can be located accurately is by applying a known pressure of 20 mm. of mercury and marking the level to which the mercury rises. This procedure is called "calibrating the manometer."

In figure 2, the bore of the tube between the 0 and the 20 mm. graduations is less than the bore of the ideal tube shown in figure 1. Hence a smaller volume of mercury is required to fill the tube between these two graduations than was required for the ideal tube, and so the mercury level will fall less in the reservoir while the level is rising in the tube from the 0 to the 20 mm. graduation than it did for the ideal manometer. Consequently, the 20 mm. graduation will be higher on the scale than for the manometer shown in figure 1.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

Alabama: Montgomery, July 12-15. Chairman, Dr. S. W. Welch, Montgomery.

Connecticut: Hartford, July 12-13. Sec., Dr. Robert L. Rowley, 79 Elm Street, Hartford.

District of Columbia: July 12. Sec., Dr. Edgar P. Copeland, Suite 110, 1801 Eye Street, Washington.

Hawaii: Honolulu, July 11-14. Sec., Dr. James A. Morgan, Young Bldg., Honolulu.

Massachusetts: Boston, July 12-14. Sec., Dr. Frank M. Vaughan, 144 State House, Boston.

Missouri: St. Louis, July 13-15. Sec., Dr. James Stewart, Jefferson City.

South Dakota: Huron, July 19. Dir. Medical Licensure, Dr. H. R. Kenaston, Bonesteel.

Washington: Seattle, July 11. Basic Science Examination, Seattle, July 7-8. Ass't. Director, Mr. George L. Berger, Olympia.

West Virginia: Martinsburg, July 26. Commissioner, Dr. W. T. Henshaw, Charleston.

Kansas February Examination

Dr. A. S. Ross, secretary of the Board of Medical Registration and Examination, reports the written examination held at Topeka, Feb. 8, 1927. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Seven candidates were licensed by reciprocity. The following colleges were represented:

PASSED

Book Notices

Child Guidance. By Smiley Blanton, B.S., M.D., Director Child Guidance Clinic, Minneapolis, Minnesota, and Margaret Gray Blanton. Cloth. Price, $2.25. Pp. 301. New York: Century Company, 1927.

The Child Guidance Clinic of Minneapolis has achieved national note through the work of Dr. Smiley Blanton and Mrs. Blanton. Their common sense methods and conservative selection of a point of view, not entirely that of the behaviorist or the psychanalyst, and their successful results in the cases of numerous "problem children" sent to them for study, have made them recognized as authorities in the field concerned. In the present volume the various chapters discuss every phase of the training of the child, including his physical reactions to life, his mental reactions, and the attitude of the parents. Of especial value are the sections on discipline, on education concerning matters of sex, and on personal study of the child, all of which are discussed in a most interesting and delightful manner. Above all, the book emphasizes the importance of thinking with the point of view of the child, rather than with that of the parent. Unfortunately, most of the toys, most of the nursery equipment, and almost everything that is developed for the child is developed from the point of view of "sales-appeal" to the parent. Frequently the interests of the child are completely at variance with this point of view.

Health Supervision and Medical Inspection of Schools. By Thomas D. Wood, A.M., M.D., College Physician, Teachers College, Columbia University, and Hugh Grant Rowell, A.B., M.D., Physician to the Horace Mann Schools. Cloth. Price, $7.50 net. Pp. 637, with illustrations. Philadelphia: W. B. Saunders Company, 1927.

Within recent years there has been an increasing interest in the problem of school health supervision. Because of the intimate contacts of children in the schools, an easy path is opened for the spread of communicable diseases. In addition, in the school the opportunity is presented for the discovery and correction of the great mass of major and minor physical defects which handicap the pupil in mental and physical growth and in development. Modern school health work has availed itself of the progress that has been made in the fields of medicine and of education, so that much has been added to the traditional program of medical inspection. Examinations are more thorough, in many instances including, in addition to the routine physical inspection, urine and blood examinations, metabolic tests, and anthropometric measurements as well as the exact measurement of deficiencies in sight and hearing. In their book, the authors have presented the best methods used in the schools throughout the country in carrying on a program of health supervision. They give a thoroughly practical and comprehensive system. The procedures recommended are those which are best adapted to bring to the pupil the maximum of health, physical well being and healthful surroundings. The examinations necessary to determine the health and physical status of the child are discussed, and the duties of the physican, nurse and teacher in carrying them out are stressed. The provisions needed for the handling of the defective child are also dealt with in a most thorough manner. Frequently, the most difficult problem which the school authorities are called on to deal with is the means whereby the correction of ill health and physical defects can be brought about. The authors discuss the methods of handling this situation. In some instances, because of the scope of certain of the fields, there has necessarily been limitation of the material to the mere pointing out of the essentials, as in the chapters on mental and social hygiene and on mental tests. On the other hand, the authors have done much to show the many sides to the problem of health supervision in the school, and have discussed almost every phase of it to some extent. At times they have been at fault in bringing forward their material without drawing any definite conclusions from it. The book will be found most valuable to all those who are concerned with the health of the child in the school—to school physicians, nurses, administrative officers, teachers and mothers. It might serve as a useful textbook for those engaged in the teaching of school hygiene and sanitation.

Handbuch der normalen und pathologischen Physiologie: Mit Berücksichtigung der experimentellen Pharmakologie. Herausgegeben von A. Bethe, G. v. Bergmann, G. Embden, und A. Ellinger. Band XVII. Correlationen 3. (J/XVI-XXI. Wärme- und Wasserhaushalt. Umweltfaktoren. Schlaf. Altern und Sterben. Konstitution und Vererbung). Paper. Price, 84 marks. Pp. 1204, with 179 illustrations. Berlin: Julius Springer, 1926.

This is the last volume of the Normal and Pathologic Physiology that was sent for review. It is also the last volume of the series. But the series has not been published entirely. In fact, only six volumes have appeared and been reviewed in The Journal. Various physiologic odds and ends are discussed by twenty-eight contributors. This volume embraces articles on pathology and pharmacology of fevers and hypothermic states; hibernation; diabetes insipidus; water metabolism; the pathology and pharmacology of edema and inflammation; the physiologic action of light, including effects of the roentgen rays and of radium; influence of baths under normal and pathologic conditions; the physical factors and influence of climate; sleep and allied states (hypnosis and hypnotics); senescence; death, and the significance of constitution in the field of psychiatry. As indicated in reviews of some of the other volumes, the collaborative efforts of some of the German scientists in this field command not only our admiration but also our gratitude. A compilation and critical evaluation of the existing physiologic literature was sorely needed since the appearance of Nagel's Handbook, which is now antiquated. This set of books must be on the shelves of every institution that lays emphasis on graduate work in the biologic sciences. As a source of information of bibliographic references, this set of books (when all have been published) will be indispensable, although the cost of the volumes seems unusually high. As one reads through the volume with its many technical expositions and attempts at elucidating the nature of living processes in its diverse expressions, one is struck by the immense amount of effort designed to solve the problems. Von Haller certainly had an easy job when compiling his Elementa (1755) compared with the herculean task he might have imposed on himself in this age. Obviously the volumes bear a strong German impression. The absence of references to foreign (particularly American) investigators is no doubt due to the unavailability of the literature since the war because of the general poverty of the universities and their scientists.

Surgical Anatomy of the Human Body. Volume II, Upper Extremities, Neck, Shoulders, Back, Lower Extremities. By John B. Deaver, M.D., Sc.D., LL.D., Surgeon-in-Chief to the Lankenau Hospital, Philadelphia. Second edition. Cloth. Price, $12 per volume; $36 for the three volumes. Pp. 854, with illustrations. Philadelphia: P. Blakiston's Son & Company, 1926.

Anatomy is a vast subject, and unless one is constantly teaching it one is not likely to have detailed knowledge. The average student leaves medical school with only a confused jumble of terms to show for his two years of study. It is really the dead language course of the medical curriculum, and bears the same relation to surgical anatomy that postmortem pathology bears to living or surgical pathology. The one presents the "chassis" unassembled, its component parts represented by muscles, nerves, vessels and viscera, and a word memory to fix them. The surgeon learns his anatomy through the repeated visualization of structures and their relationships, and he continues to be conversant with anatomic detail long after he has forgotten the nomenclature. Surgical anatomy is the study of surface landmarks, the identification of living structures in situ, through an incision rather than when they are displaced by dissection, and it correlates anatomy with pathology. Deaver presents his material from the latter point of view, and in almost every description of importance he groups his facts about and shows their relationship to the surgery of the particular region under consideration. The text is a fine piece of work; the illustrations, while not colored, are many and excellent. The volume is limited to the extremities, neck, shoulder and back, which is a convenient arrangement for regional study.

Health Record for Children. By J. Theron Hunter, M.D. Cloth. Price, $1. Pp. 52. Baltimore: Williams & Wilkins Company, 1927.

An excellent, straightforward book, to be recommended to any mother who will write a few notes on her child's family and developmental history by jotting down illnesses as they come along. Each page covers a subject indicating to the mother the most important features to be recorded. There are charts for weight, dates and duration of colds and sore throats; and particularly suitable is the chart for temperature and a few other essentials which the parent should record in any acute infection. In a second edition certain details might well be rearranged; for example, the page for dates of walking, talking and illnesses would come more naturally immediately before the temperature charts instead of before birth.

Traité de physiologie normale et pathologique. Publié sous la direction G.-H. Roger, professeur de physiologie à la Faculté de médecine de Paris, et Léon Binet, professeur agrégé de physiologie à la Faculté de médecine de Paris. Tome VII. Sang et lymphe: Réactions d'immunité. Par. M. M. Ch. Achard, A. Besredka, et autres. Cloth. Price, 65 francs. Pp. 502, with illustrations. Paris: Masson & Cie, 1927.

This volume on normal and pathologic physiology deals with blood, lymph and immunity. It is a composite effort of eleven authors with chapters on the morphology of the blood, hemoglobin and its derivatives, respiratory albuminoids of invertebrates, blood plates, bone marrow, blood coagulation, hemorrhage, blood transfusion, the lacunar system (including edema and dehydration), lymph and lymph production, lymph glands, immunity (this chapter by Bordet), and anaphylaxis. Each chapter has limited literature references. The book as a whole is weakened by the absence of an index at the end so that the contents must be hunted up by the scant aid of the table of chapters. The chapter by Bordet on immunity is particularly good. It seems significant, however, that in such an ambitious monograph on the blood and lymph, with chapters on hemorrhage, edema and transfusion, there should be no chapter on the various anemias. One is also struck by the fact that in the chapter on the physiology and pathology of the blood plates no reference appears to be made to the recent work of Howell on the significance of the blood plates in hemophilia. The book as a whole, however, is readable, lucid, reasonably comprehensive and down to date.

Index and Handbook of X-Ray Therapy. By Dr. Robert Lenk, Privat-Dozent of Medical Roentgenology, University of Vienna. With a foreword by Professor Holzknecht. Translated by T. I. Candy, M.B., B.Ch., D.M.R.E., Hon. Radiologist, Royal Gwent Hospital, Newport, Mon. Cloth. Price, $2.25. Pp. 121. New York: Oxford University Press, 1926.

This is an English translation of an excellent handbook meant primarily to instruct the general practitioner by outlining the indications for roentgen-ray therapy, and secondarily for the roentgenologist by providing him with a definite and proved scheme for the treatment of diseases by roentgen rays. The book is arranged in two sections. In the first section the mode of action of roentgen rays, effects of treatment, including the various reactions, prognosis and adjuvant treatment, are considered in a clear, concise and practical manner. The second section concerns itself with the use of roentgen rays as the therapeutic agent of choice in some sixty selected diseases. These are arranged alphabetically and a brief statement concerning the mode of action, reactions, course, duration and result of treatment is made for each. The formulas are all in terms of the Holzknecht unit, which detracts from the value of the book to the specialist in this country, where other standards of dosage are more commonly used. However, the author anticipates this in his general discussion of treatment formulas and agrees that roentgen-ray therapy is not purely a technical problem but is subject to variation for each individual case. The book contains a wealth of material of great interest to the general practitioner who wishes to have some idea of the possibilities of roentgen-ray therapy, and enables him to advise his patient intelligently to seek this form of therapy and to discuss in a general way the many questions which are always asked of him. The author's experience with roentgen-ray therapy has been extensive, and there is probably more than the element of optimism when he suggests the use of roentgen rays in such conditions as gallstone colic, gastric ulcer, badly functioning gastro-enterostomy, and otosclerosis. Although the index does not include the contents of the second section, the diseases discussed are alphabetically arranged and are easily referred to. The superfluous and needless description of apparatus and a discussion of elementary physics usually found are omitted. For the practitioner the book fills a long felt want and contains an unusual amount of data to which he can quickly and profitably refer.

A Textbook of Exodontia: Exodontia, Oral Surgery and Anesthesia. By Leo Winter, D.D.S., Professor of Oral Surgery, New York University College of Dentistry. Cloth. Price, $7.50. Pp. 364, with 329 illustrations. St. Louis: C. V. Mosby Company, 1927.

This is a valuable book for the student or the practitioner working in the field of exodontia and minor oral surgery. The author treats the several divisions of the work with great care and thoroughness. Practical ideas mark the chapters dealing with pathology and diagnosis; anesthesia, both local and general; extraction of teeth that are in normal and abnormal position; technic; treatment of complications; removal of impacted teeth; treatment of fractures and dislocations, and accidents. They can be followed and carried out not only by the specialist but also by any one possessed of average professional skill and ability. The many photographic and roentgenographic illustrations further enhance the value of this work.

Ergebnisse der gesamten Medizin. Herausgegeben von Prof. Dr. Th. Brugssach, Oberarzt der II. medicinischen Klinik der Charité in Berlin. IX.—Angina pectoris. Von Prof. Dr. Hans Kohn. Paper. Pp. 209-276. Berlin: Urban & Schwarzenberg, 1926.

The author has condensed into these sixty-five papers a comprehensive summary of the present status of our knowledge of angina pectoris. The historical background is given briefly but in full. From this are traced the various views of the symptom complex or, as the author would consider it, of the disease entity. The views of the different authors are considered entirely and fairly, in spite of the somewhat partisan bias of the author. The evidence in support of the hypothesis which he believes to be the only logical explanation for the symptoms is carefully developed and conclusively presented. He considers that angina pectoris is a definite disease entity and not a symptom complex, and that it is always due to a narrowing of the coronary vessels, causing an ischemia of the heart muscles. This may be due to anatomic changes in the vessels, such as atheromatous syphilis or endo-arteritis, with a possible thrombosis superimposed on either of them, or, rarely, to an embolus. In the absence of sufficient anatomic changes, he holds that the same phenomena characteristic of angina pectoris can be produced by an active vasoconstriction of the coronaries, and that even in the presence of anatomic changes the attack itself may be precipitated by a vasoconstriction. The sudden death is due to an ischemia of the heart muscle and ventricular fibrillation. The evidence gathered is convincing. Similar views have been held, in part at least, by others, as von Neusser, but have never been so clearly presented or supported by so thorough and logical a brief. This admirable exposition should be read generally by physicians, and not only by those especially interested. It is impossible to convey in a brief review the amount of valuable material in these few pages. There is a full index to the literature used. It is unfortunate that the construction is at times unnecessarily involved.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits. Books listed in this department are not available for lending. Any information concerning them will be supplied on request.

Principles of Chemistry. An Introductory Textbook of Inorganic, Organic and Physiological Chemistry for Nurses and Students of Home Economics and Applied Chemistry, with Laboratory Experiments. By Joseph H. Roe, Ph.D., Professor of Chemistry, George Washington University Medical School. Cloth. Price, $2.50. Pp. 378, with 30 illustrations. St. Louis: C. V. Mosby Company, 1927.

Another textbook for nurses telling more than they ever will need to know.

Universal Knowledge. A Dictionary and Encyclopedia of Arts and Sciences, History and Biography, Law, Literature, Religions, Nations, Races, Customs and Institutions. Edited by Edward A. Pace, Ph.D., D.D., and others. Volume I. Cloth. Price, $6.25 per volume; $75 per set of twelve volumes. Pp. 1694, with illustrations. New York: Universal *Knowledge Foundation, Inc., 1927.*

New encyclopedia with many distinguished medical contributors.

Taschenbuch der praktischen Untersuchungsmethoden der Körperflussigkeiten bei Nerven- und Geisteskrankheiten. Von Professor Dr. V. Kafka, Leiter der serologischen Abteilung der psychiatrischen Universitätsklinik u. Staatskrankenanstalt Friedrichsberg, in Hamburg. Third edition. Paper. Price, 6.60 marks. Pp. 114, with 42 illustrations. Berlin: Julius Springer, 1927.

Vest pocket guide for neurologic examinations.

The Mind and Its Mechanism: With Special Reference to Ideo-Motor Action, Hypnosis, Habit and Instinct, and the Lamarckian Theory of Evolution. By Paul Bousfield, M.R.C.S., L.R.C.P., and W. R. Bousfield, K.C., F.R.S. Cloth. Price, $4. Pp. 224. New York: E. P. Dutton & Company, 1927.

Highly complex consideration of theories of mind action, concluding that mind patterns are heritable.

Röntgentherapeutisches Hilfsbuch für die Spezialisten der ubrigen Fächer und die praktischen Aerzte. Von Dozent Dr. Robert Lenk, Assistent am Zentralröntgenlaboratorium des allgemeinen Krankenhauses in Wien. Mit einem Vorwort von Professor Dr. Guido Holzknecht. Third edition. Paper. Price, 4.80 marks. Pp. 81. Vienna: Julius Springer, 1927.

Handbook of roentgen-ray technic.

A Practical Treatise on Diseases of the Skin for the Use of Students and Practitioners. By Oliver S. Ormsby, M.D., Clinical Professor and Chairman of the Department of Dermatology, Rush Medical College of the University of Chicago. Third edition. Cloth. Price, $11. Pp. 1262, with 524 illustrations. Philadelphia: Lea & Febiger, 1927.

New edition thoroughly revised based on extensive experience in teaching and practice.

Röntgen Rays in Dermatology. A Handbook for Practitioners and Students. By L. Arzt, M.D., and H. Fuhs, M.D., Professors at the Riehl Clinic for Dermatology and Syphilology, Vienna. Translated by C. Kevin O'Malley, M.C., M.B., B.A.O. Cloth. Price, $6. Pp. 202, with 57 illustrations. New York: William Wood & Company, 1927.

Translation of monograph giving current practice of Viennese school.

Baby's Daily Exercises. A Manual of Exercises for Infants from Five Months to One Year of Age. By Edward Theodore Wilkes, B.S., M.D., Assistant Pediatrician, Out-Patient Department, New York. Cloth. Price, $1. Pp. 77, with illustrations. New York: D. Appleton & Company, 1927.

The baby's daily dozen thoroughly elucidated.

Should We Be Vaccinated? A Survey of the Controversy in Its Historical and Scientific Aspects. By Bernhard J. Stern, Instructor of Sociology, Columbia University. Cloth. Price, $1.50. Pp. 146. New York: Harper & Brothers, 1927.

An enlightened layman proves that sanitation plus vaccination are necessary to control smallpox.

Venereal Disease: Its Prevention, Symptoms and Treatment. By Hugh Wansey Bayly, M.C., Hon. Sec. Society for the Prevention of Venereal Disease. Third edition. Cloth. Price, 10/6 net. Pp. 242, with 77 illustrations. London: Faber & Gwyer, Ltd., 1927.

New edition with special reference to recent investigations.

Year Book of the Pennsylvania Tuberculosis Society for 1926. Paper. Pp. 20. Philadelphia: Pennsylvania Tuberculosis Society, 1927.

La cesárea extraperitoneal y la transperitoneal suprasinfisaria sus modalidades tecnicas y sus finalidades terapéuticas Por Mateo Carreras Paper Pp 106, with illustrations Madrid Javier Morata, 1927

Miscellany

A NEW STAIN FOR BLOOD FILMS

Nyfeldt *(Ugeskrift for Læger)* has worked out a new method which gives a very clear distinction between the eosinophil and the pseudo eosinophil leukocytes, so that a mistake is out of the question This method is practiced as follows

1 The specimen is fixed in absolute methyl alcohol for five minutes, the alcohol being pressed out with several layers of blotting paper

2 It is stained for five minutes with a solution of 1 part of May Greenewald s stain and 2 parts of Epstein's lithiontoluidin blue, after which is is,

3 Washed well in water and then,

4 Differentiated for five seconds in a watery saturated trinitrophenol solution and then,

5 Washed well in water and dried with blotting paper

The color effect obtained by this method is the following

The chromocytes are stained a beautiful light green, while the polychromatic chromocytes are light green to bluish green

The eosinophil granulations are shining green, while the pseudo eosinophil granulations and the neutrophils are dark bluish purple

Basophil granules are bluish black, while the azurophil granules are carnelian red The nuclei are well stained in these different cells, but seem to be mode easily stained than are the Pappenheim stained specimens

The plasma of the lymphocytes is either dark blue in the small ones or light blue in the big ones The plasma of the monocytes is often filled with a dust shaped light purple granulation

The malaria plasmodium seems to be blue in the light green chromocyte body, while the chromatin grain is black-red, so that there is a good contrast

GASTRIC HYPERTONUS AND GASTROPTOSIS

Arthur F Hurst (*Guy's Hosp Rep* **77:22** [Jan] 1927) concludes that the types of stomach commonly diagnosed by radiologists as hypertonic and as dropped, respectively, are quite incorrectly named Experiments with stomach tubes connected with a manometer and more recent radiologic investigations have shown that the tone of the normal stomach adapts itself to the volume of its contents so that the pressure within remains constant Every radiologist is familiar with the fact that the upper level of the contents may be just under the diaphragm, whether it lies almost horizontally with the lowest point of its greater curvature two inches above the interiliac line, or vertically with the greater curvature dipping into the true pelvis This shows that the intragastric pressure and therefore the tone are the same in the two stomachs Yet the first stomach is commonly called hypertonic, the second is not indeed called hypotonic, a term rightly reserved for cases in which the upper level of the contents is abnormally low, but it is said to have "dropped" It is clear that the contrast between the two stomachs is erroneously described—a term indicating an abnormality of tone being contrasted with one indicating an abnormality in position The former is obviously wrong because the tone is the same in the two stomachs The latter is equally incorrect, for "gastroptosis," or dropping of the stomach, should indicate that the stomach has fallen It is true that in so called gastroptosis the stomach falls on standing from the position it occupies when lying, but every stomach does this, and there is no evidence that it has fallen from a higher position than it once occupied in the erect position

So called gastroptosis is quite common in people with excellent *abdominal muscles, who have always been thin,* and it also occurs, though less frequently, in comparatively stout individuals On the other hand, the so-called hypertonic stomach may exist in people who have lost much weight and whose abdominal muscles have become very weak Nothing, in fact, will make such a stomach drop materially, just as nothing will make the so-called dropped stomach rise to the level of the average stomach. Therefore, the usual explanations given for the remarkable difference between the appearances of the so-called hypertonic and the so-called dropped stomach are incorrect. The only satisfactory explanation is to regard the difference between the two types of stomach as due to anatomic variations from the average normal length.

The stomach swings between the part of the esophagus that passes through and is fixed to the diaphragm about one inch above the cardia, and the junction between the duodenal bulb and the descending retroperitoneal portion of the duodenum. If it is short, it assumes the diagonal or almost horizontal position of the so-called hypertonic stomach; if it is long, it assumes the vertical position with the steeply ascending pyloric part of the so-called dropped stomach. These two types of stomach should be renamed, respectively, the short stomach and the long stomach, and they should be regarded as nothing more than normal anatomic variations from the stomach of average length. The short stomach is often associated with hyperchlorhydria and predisposes to duodenal ulcer, with which it is therefore frequently associated. When other forms of stomach are found with duodenal ulcer, some reflex or organic interference with the pyloric sphincter is generally present; the typical short form is restored when the ulcer heals. The long stomach is generally associated with a normal or low gastric acidity, and it appears to predispose to gastric ulcer. The conception of a "hypertonic stomach" is the invention of the radiologist to explain an appearance which is due to something else. A "hypotonic stomach," corresponding with the "atonic dilatation of the stomach" of the preradiologic period, does exist, but in most cases in quite a different form from what is commonly described. In the absence of organic disease it is rare and never of any clinical significance, being found incidentally in routine radiologic examinations: the upper level of the gastric contents is lower than usual without any corresponding excess of gas being present in the fundus. As tone is completely independent of peristalsis, this does not result in any delay in evacuation, and does not give rise to symptoms.

Severe hypotonus rarely, if ever, occurs except as a complication of pyloric obstruction, when it develops in exactly the same way as the myocardial hypotonus which may accompany the dilatation of the left auricle in mitral stenosis. The gradual development of pyloric obstruction leads to hypertrophy of the muscular wall of the stomach, which to some extent compensates for the difficulty in evacuation. A time soon comes, however, when the stomach is never completely empty, and, if food continues to be taken in the usual amount, it gradually becomes more and more dilated. In the early stages the stomach is still capable of contracting to its normal size if it is completely evacuated by a tube or by vomiting, no loss of tone having occurred. But gradually the postural tone of the musculature adapts itself to the new conditions, so that evacuation is no longer followed by a complete return to the normal tone of the empty stomach; some true hypotonus has now developed. Only in neglected cases, which are rare nowadays, does anything approaching complete atony occur; in such cases it is essential to give a course of gastric lavage and to keep the stomach empty during most of each day for a week or more before operation, as, unless tone is restored, the gastro-enterostomy will not work satisfactorily and death is likely to follow. Unless great care is taken, atony is likely to be diagnosed in many cases in which it does not occur. In pyloric obstruction a considerable accumulation of clear gastric juice may be present when fasting in the morning, together with more or less food if the obstruction is organic. The opaque meal falls through it, and its upper surface may be mistaken for the upper surface of the gastric contents, but more careful inspection will show that the latter is some inches higher up or possibly even in the normal position, though it is difficult to recognize, as the accumulation of gastric juice is only slightly more opaque than the gas bubble immediately above it. In such cases the roentgen-ray examination should be repeated after the stomach has been evacuated with a tube, in order to estimate the tone of the stomach and to obtain a clear view of the pyloric vestibule, which would otherwise be filled with the translucent resting contents of the stomach instead of the opaque meal. Hurst protests against the term "orthotonic" stomach. It is quite meaningless. The so-called orthotonic stomach is simply the stomach of average length; it may occasionally be actually hypotonic, and, if such a condition as true hypertonus ever occurs, there is no reason why it should not become hypertonic.

Questions Not Permitted to Be Asked Medical Expert

(Commonwealth v. Marshall (Pa.), 135 Atl. R. 301)

The Supreme Court of Pennsylvania does not find reversible error in the exclusion of certain questions propounded to a physician who was called as a witness by the defendant in this homicide case. One of the questions was properly excluded because it concerned a subject sufficiently within common knowledge to render an expert opinion unnecessary. Others of the questions sought to have the witness testify that two separate necropsy reports, made by physicians who appeared at the call of the commonwealth, did not contain sufficient evidence to warrant the conclusion that death resulted from the cause therein assigned. These documents were obviously form reports and did not attempt to give more than the briefest outline of the major conditions found on examination of the body. That an attack on the conclusions of the examining physicians, as to the cause of death, could not properly be made by a critical view of these form reports was clear, and offers of testimony to accomplish that end were rightly refused.

In other instances the defendant sought to have his medical expert base his opinion, not on his own statement of existing facts, nor on facts embodied in a hypothetic question, but on the testimony given by the physicians who had made the necropsies. While it is permissible for an expert to express an opinion based on the nonconflicting testimony of others, when such testimony is assumed to be true, this should be allowed only when the prior testimony embodies a set of facts of such completeness as to be susceptible of being put in the form of a valid hypothetic question. The testimony of the commonwealth's physicians contained much of fact and much of opinion; it did not necessarily mention all the conditions existing in the body of the deceased when it was examined, and, in fact, the coroner's chief physician testified that all that had been observed in making the necropsy had not been brought out in the testimony, though there was no assignment of error complaining of an insufficient statement of facts to permit the expression of opinion by the commonwealth's witnesses, who said that they deduced their ultimate opinion from all they had observed in making their necropsies. Then some of the questions put to the defendant's medical expert would have required him to draw his own conclusions of fact, from the prior testimony, on which to base his opinion. This the law would not permit. Opinion testimony may be given only on a set of definitely established or assumed facts; all balancing of testimony and deductions of fact therefrom must be made by the jury.

Instead of having the medical expert by expressing his own professional views on an assumed state of facts help the defendant's case, thus rebutting the expert testimony of the prosecution, the effort was apparently to have him condemn the medical witnesses of the commonwealth by expressing his opinion that, on the data considered by them, it could not properly be said that the death of the deceased was attributable, as they had said, to "compression of the neck." Practically all the questions for this purpose were leading, in the sense that they suggested the answer desired, and were objectionable on that score if for no other reason. Furthermore, the defendant's expert described in detail the various physical conditions and signs which usually appeared, and were to be scientifically expected, in cases of strangulation. The jury had this testimony to compare with that of the physicians called by the commonwealth, and, with the assistance of counsel, could determine whether or not the signs and conditions described by the defendant's expert appeared in the case. It was for them, the triers of the facts, to decide that question, not for him to do so by answering a comprehensive and suggestive question put by counsel for the defendant, who, at the end of the witness' description of what should appear in such cases, asked him to say whether or not the telltales which he had just enumerated and described were present in the examination that one of the physicians for the commonwealth had made, and of which the witness had read a report. The true test was not whether, from certain parts of the testimony for the commonwealth, he could say what was the cause of the death, but whether or not, considering all the data shown to have been considered by experts on the other side, it could properly be told therefrom what the cause of death was; or, if you please, on that data, assuming it to be correct, whether or not he could state the cause of death. This would have given him the proper opportunity to assert, if in his view such was the fact, that the data did not afford a sufficient basis for an opinion concerning the cause of death, and hence that he could not express one.

Proper Procedure After Revocation of License

(Oliver v. State ex rel. State Board of Medical Examiners et al. (Okla.), 251 Pac. R. 31)

The Supreme Court of Oklahoma says that respondent Oliver, a duly licensed physician and surgeon, was informed against by the state board of medical examiners on a charge of being guilty of unprofessional conduct. He was thereafter duly cited to answer the complaint, and did answer it, denying specifically the acts complained of. Subsequently, the state board heard the complaint, and evidence was introduced, after which the board found against the respondent, and ordered that his license as a physician be revoked. He gave notice of appeal to the superior court of Pottawatomie County, and also gave notice that he would apply to that court for a writ of certiorari, and an order requiring the board to certify all the records of the proceedings against him to that court. Within three days thereafter he filed his petition in the superior court of Pottawatomie County, where one of the members of the board resided, and the court issued its writ of certiorari, and ordered the board to certify the entire record to the court. Then the attorney general, on behalf of the board, moved to dismiss the writ and order, for the reason that the state statutes provide proper and adequate remedy by appeal, and that therefore the writ and order were improperly issued and made. The court sustained the motion, and dismissed the proceeding pending in the superior court. The sole question presented was: Did the superior court commit error in dismissing the writ and vacating the order? The supreme court holds that it did, and reverses its judgment, for further proceedings.

It is to be observed that, although section 33 of chapter 59 of the session laws of 1923 provides for an appeal and trial de novo (anew), yet no procedure or method of perfecting the appeal is provided for. The uncertainty of this statute was no doubt responsible for the fact that the respondent gave both notice of appeal and notice of his intention to apply for a writ of certiorari. It was quite evident that he desired to have the matter heard de novo in the superior court, as he was entitled to, and, because of the inadequacy of the statute, was fearful of taking one horn of the dilemma, lest the medical board take the other. It is not the province of this court to lay down the rules or formality governing an appeal in such cases, but it is proper for this court to say that he was entitled to a trial de novo before being deprived of the benefits of his life's profession. The methods of appeal from the various boards, commissions and courts are many and varied, and, as no procedure had been laid down for such an appeal as the respondent desired, it was impossible for him to know which method to pursue. The general rule is that the writ of certiorari will lie when there is no adequate remedy by appeal or otherwise.

The respondent was entitled to have the matter heard de novo in the superior court. This had not been done. In the opinion of the supreme court, the appeal provided for by the act under consideration was not adequate and complete, and therefore certiorari was the proper procedure for bringing the record of the board to the superior court. The supreme court must conclude that the trial court abused its discretion in dismissing the writ and vacating its order to the medical board to certify its records to the superior court. It might be that the medical board had certified the entire record to the superior court by reason of the verbal notice of appeal given by the respondent. In that case the writ would be useless; but the trial court should proceed with a hearing of the case on its merits.

Physician Not Wholly and Permanently Disabled

(Corsaut v. Equitable Life Assur. Soc. (Iowa), 211 N. W. R. 222)

The Supreme Court of Iowa says that the plaintiff was the widow of a physician and the beneficiary of a policy of insurance issued on his life, Jan. 30, 1922. The insured died, Dec. 31, 1923. A premium due on his policy, Jan. 19, 1923, was not paid. But the policy contained a provision that if the insured became wholly and permanently disabled before the age of 60, the society would waive the subsequent premiums; and the plaintiff alleged that for some time prior to Jan. 19, 1923, and thereafter until the date of his death, the insured was totally and permanently disabled by disease, and was totally insane and incompetent to transact any business or cause it to be transacted by any one in his behalf. The question was whether, on the record, the trial court erred in submitting the case to the jury, which returned a verdict in favor of the plaintiff, or whether the court should have directed a verdict in behalf of the defendant.

There was no provision for "partial disability" or for disability that should incapacitate one from performing his "usual occupation." The policy provided but one condition under which premiums were waived by the company, and that was, "if the insured becomes wholly and permanently disabled before age 60." This court cannot give to these words any other and different interpretation than their usual and ordinary meaning. "Wholly and permanently disabled" cannot logically be construed to mean partially disabled, or disabled to a limited degree, or disabled from doing certain things while able to do others. Under the record it could not be said that this case presented an instance of an insured who was "wholly and permanently disabled."

Undoubtedly the insured had a mental breakdown, and this began to be noticeable in 1922; but at or about the time that the premium in question was due, and for several months thereafter, the insured was carrying on the practice of his profession, was treating patients, and, so far as the record disclosed, without making mistakes in the very delicate and, in a sense, dangerous business of administering medicine. The only specific instance in the record looking toward a lack of judgment in this regard was an instance in which as late as December, 1922, physicians closely acquainted with him evidently deemed him competent to undertake the delicate task of administering an anesthetic, and it appeared that he administered too much of it, and it became necessary to resuscitate the patient. In the light of common knowledge it could not be said that this incident was evidence of "total and permanent disability." The number of patients shown by the books of the physician to have been treated during the period from January to June, 1923, ran into the hundreds. According to the testimony of the office girl, some of these entries were erroneous, and the physician doubtless made charges against people whom he did not treat. He was forgetful and negligent and subject to spells of exhilaration and of depression, but the undisputed fact remained that during this entire period he was in regular attendance at his office, and was continuously engaged, more or less, in treating patients, administering medicine, and practicing his profession. In June, 1923, he made an examination of an applicant for insurance, filling out the somewhat extensive blank form for such examination in detail, and received a check therefor, and indorsed the same.

Without reviewing the record further, this court is constrained to hold that a verdict to the effect that during this period the insured was "wholly and permanently disabled" was contrary to the record in the case, and could not be permitted to stand. The trial court should have sustained the defendant's motion for a directed verdict at the close of all the testimony. No other conclusion is warranted under the record in this case under the terms of the policy in question and the rules of law applicable thereto as heretofore announced by this court. The plaintiff was charged with the burden of establishing that the insured was "wholly and permanently disabled." In this she failed. The judgment of the district court in favor of the plaintiff must be, and it is, reversed.

Liability for Death from Procuring a Miscarriage

(State v. Shortridge (N. D.), 211 N. W. R. 336)

The Supreme Court of North Dakota, in affirming a judgment of conviction of murder in the second degree, charged to have been committed by the defendant by employing an instrument or other means to procure the miscarriage of a named woman, and in that connection inflicting a wound resulting in her death, says that the defendant testified to symptoms present at the time the woman came to his hospital which indicated that a miscarriage was imminent. He explained the progressive character of the hemorrhage, and described the symptoms pointing to the necessity for the removal of the fetus, and detailed the operation. He denied the use of any instrument in connection therewith. On the other hand, the expert testimony disputed any contention that the tear in the uterus resulted from a natural abortion. There was also evidence which would warrant the jury in finding that the condition which existed until the woman consulted the defendant was the normal condition of a pregnant woman, and that there was no necessity for the performance of the operation which he admitted that he did perform. But, aside from the affirmative evidence of these facts, the jury was justified in taking into consideration the conduct of the defendant after the death of the patient. This conduct could properly be judged in the light of common experience and if, when so considered, the acts of the defendant were best accounted for by considering them as done to conceal a prior course of criminal conduct concerning the deceased, the jury might properly consider his actions as evidence of the crime charged.

In a petition for rehearing, which was denied, it was contended that the trial court erred in not instructing the jury fully on the defense indicated in the defendant's testimony to the effect that a miscarriage was imminent at the time the woman consulted him, and that the operation which he performed was necessary to save the life of the patient. It was said that the woman might very easily have inflicted on herself such a wound as would make it appear to the physician that a miscarriage and curettement were imminently necessary, and that a physician might not be held criminally responsible for an operation which he, in good faith and in the exercise of his best skill and understanding, believed to be necessary to save the patient's life. The assignment of error, in support of which this argument was advanced, was the refusal of the trial court to instruct the jury that the burden was on the state to negative that the defendant, in good faith and in the exercise of his best skill and understanding, believed the operation was necessary to save the patient's life.

The instruction given defined murder in the second degree as homicide perpetrated wilfully, unlawfully and feloniously, without any design to effect death, by a person engaged in the commission of a felony, and if the felony charged was the felony of procuring an abortion, then it was murder in the second degree. In defining the felony the defendant was charged with being engaged in committing at the time of the acts resulting in the death of the woman, the instruction defined the crime of procuring an abortion substantially in the language of section 9604 of the compiled laws of North Dakota of 1913, which makes it a felony for any person to employ an instrument or other means, with intent thereby to procure the miscarriage of a pregnant woman, unless such an operation is necessary to preserve her life. From these two instructions, following as they did the statutory definitions of murder and of abortion, it is readily apparent that the giving of the instruction requested would involve the writing into the statute of an exception to the effect that, when a physician procures the miscarriage, he shall not be criminally responsible, if he, in good faith, believed his acts to be necessary. The statutes of some states embody such an exception. In the absence of such an exception in the statute, however, either expressed or arising by fair implication, no such fact or circumstance excusing the act of a defendant is available as a defense. The North Dakota statute does not contain any express exception or any language from which this court thinks one may fairly be implied. The standard by which to determine the necessity under the statute is not the good faith or bad faith of the physician, nor does it vary with the degree of skill which he possesses. It is the one standard of necessity. On the state rests the burden of proving beyond a reasonable doubt that no necessity existed. When this fact is thus proved, it is established that the operation is unlawful and, being performed voluntarily, an intent to perform the unnecessary operation must be ascribed. It is the general criminal intent that is important in such a case. In other words, criminal intent is supplied by proof showing beyond a reasonable doubt that the acts were not necessary to save life.

Delirium Tremens and Death After Herniotomy

(Valeri v. Village of Hibbing (Minn.), 211 N. W. R. 8)

The Supreme Court of Minnesota, in affirming a decision of the industrial commission awarding compensation to a widow for the death of her husband, says that the finding of the commission that a hernia was caused by the man's attempt to lift a can of garbage was sufficiently supported by competent evidence. To relieve the hernia, a surgical operation was performed. It was followed two days later by an attack of delirium tremens, and on the fourth day by the man's death. He was an Italian by birth, had once been a saloonkeeper, and habitually drank wine which he made and kept at home. There was evidence of a somewhat unsatisfactory character that for at least two weeks before he entered the hospital for the herniotomy he had been in a state of mild intoxication. For the village, which was his employer when he suffered the hernia—a right inguinal one—it was contended that the evidence did not support a finding that the hernia was a proximate cause of his death; but the court holds that the finding that the operation set into activity delirium tremens and that death was the result of the operation and the subsequent complications was supported by the evidence. To those not versed in medical science, the statement that delirium tremens may result from a surgical operation is surprising. The popular belief is that the excessive use of intoxicating liquor is always the cause of the disorder. But the medical witnesses agreed that the operation and the shock to the nervous system and the pain and suffering that followed were contributing causes to the development of the acute delirium from which the man suffered. Granting that his habitual consumption of wine was a predisposing cause of the attack, nevertheless, if the operation was the proximate cause of his death, and the hernia resulted from a strain to which he was subjected when he tried to lift the can of garbage, his dependents were entitled to compensation. To state it a little differently, even if the habit of drinking wine was a predisposing factor in bringing on the attack of delirium tremens and the man's death, nevertheless, if the injury and the operation were material factors, in the absence of which death would not have occurred when it did, his dependents were entitled to compensation.

Physician May Testify to Probable Duration of Life

(Fournier v. Zinn (Mass.), 154 N. E. R. 268)

The Supreme Judicial Court of Massachusetts says that in this action to recover damages for personal injuries sustained in a collision of automobiles a physician called by the plaintiff was allowed, subject to the defendant's exception, to state his opinion of the probable duration of the plaintiff's life. He said that, taking into account the plaintiff's physical condition if he had not received the injury complained of, he would live about nine years; that because of the accident, he would probably live about four years from that time. This evidence was admissible. Mortality tables based on selected lives are admitted in evidence. The probable length of life of the plaintiff as affected by the injury was relevant.

Society Proceedings

COMING MEETINGS

Idaho State Medical Association, Twin Falls, August 29-31. Dr J. N. Davis, Kimberly, Secretary.

Montana, Medical Association of, Missoula, July 13-14. Dr. E. G. Balsam, 222 Hart-Albin Building, Billings, Secretary.

Washington State Medical Association, Tacoma, August 29-31. Dr. C. H. Thomson, 508 Cobb Building, Seattle, Secretary.

ASSOCIATION OF AMERICAN PHYSICIANS

Forty-Second Annual Meeting, held at Atlantic City, N. J., May 3 and 4, 1927

(Concluded from page 59)

Food Iron and Its Storage in the Body

Dr. Charles S. Williamson, Chicago: By feeding liver for four months we can effect an iron storage which can obliterate an anemia of 33 per cent loss of blood. Applying these principles clinically to the hematopoietic system, we find that some patients recover and others show no effect from treatment. This difference may be nothing but the iron which has or has not been stored up. In young persons, particularly, the diet should be very rich in iron; the iron storage should be sufficient to carry them over periods of stress.

Circulatory Collapse in Diphtheria

Dr. C. W. Edmunds, Ann Arbor, Mich.: There are two methods of treatment: injection of dextrose solution and injection of solution of pituitary. The heart is not primarily responsible for the failure in circulation; therefore the periphery is at fault.

Auscultatory Gap in Sphygmomanometry

Dr. Paul D. White, Boston: The auscultatory gap is an interval of silence beginning below the systolic pressure and down for 50 mm. In hypertension cases there is a murmur present in 5 per cent. We have also been able to detect aneurysm compressing the subclavian artery at this point. A fifth sound phase is now differentiated. One may get a complete auscultatory gap, an incomplete gap or an inconstant diminution of the gap. The type most frequently observed is situated in the middle third of the pulse pressure, or sometimes at the upper end. The gap is noted by taking the systolic pressure beyond the gap. Pulse rates from 16 to 100 were recorded. Sixteen patients had dyspnea on exertion, and six had angina. The reasons for this gap may be: constriction; decrease in pressure; the type of pulse wave; failure of resonance of the arterial wall; peripheral resistance of the artery. No definite prognosis can be attached to the phenomena of the gap; the result depends on the underlying pathologic condition.

DISCUSSION

Dr. Eugene S. Kilgore, San Francisco: These observations constitute an important and serious criticism of prevalent teaching and practice of sphygmomanometry. There exists a general impression that auscultatory readings, being usually somewhat higher than palpatory, are nearer true blood pressure and less subject to variation by the personal factor of the examiner. As a matter of fact, however, the palpatory method itself yields figures a little above actual pressure, and therefore for theoretical nearness of readings to actual conditions the palpatory method would be preferable.

Diabetes Mellitus, Refractory to Insulin

Dr. Albert E. Taussig, St. Louis: A patient had a progressively severe diabetes and showed urticaria after injections of insulin. She went into diabetic coma and we had to give her enormous doses of insulin, but we were never able to make her sugar free. One day she had 1,100 units of insulin. In patients who showed little or no drop after intravenous injections, we tried hypodermic injections with no better result. We also tried fractional doses of 20 units hourly but never got them sugar free. After two months the response to insulin showed improvement and finally we were able to give a daily dose of 200 units. Finally, the insulin was brought down to 104 units daily. To find the reason for this refractory condition we took 10 cc. of the patient's blood and injected it into rabbits, but there was no result. We then tested for an allergic skin reaction without result. We tested the urine but found no trace of insulin in the urine. We have also considered the theory that insulin acts as a coferment, transforming blood sugar into glycogen or lactic acid. In some persons the other constituent (muscle phosphate) may be lacking or may be present in too small amounts, so that insulin is not able to do its work.

Myrtillin, a Diabetic Remedy Orally Administered

Dr. F. M. Allen, Morristown, N. J.: There are two substances present, in association in blueberry leaves: one (myrtillin) which lowers blood sugar and a substance which raises it. These two substances occur in all plants and belong to the anabolic, catabolic activities of plants. If myrtillin is effective at all, it is as effective in doses of 1 Gm. daily as in doses of 30 Gm. The effect is to stabilize blood sugar reactions when administered orally or intravenously. The results are the same when given by mouth or by vein. The effect lasts for days or even weeks. With nine tenths of the pancreas removed, there is severe diabetes, which can be controlled by myrtillin. If only one fiftieth of the pancreas is left the animals cannot survive even with myrtillin. Autopsy shows hypertrophy of the pancreas remnant. The first step in treatment is to make the urine and blood normal with insulin or diet, then to give myrtillin, and then to watch for gradual building up of tolerance. Some cases are successful; some are not. Myrtillin is harmless. It is less prompt, less powerful and less certain than insulin. It is not a substitute for insulin.

Relation of Thyroid to Calcium Metabolism

Dr. Joseph C. Aub, Boston: The blood calcium and blood phosphorus are normal in thyroid disease, but the amounts excreted are far above normal. In the normal control, thyroid administration raises the blood calcium and calcium excretion. In myxedema, calcium metabolism is lowered, but with administration of thyroid the blood calcium and the calcium excretion are raised. In one patient, a woman who had had tetany for seven years, there was a deficiency of calcium. Parathyroid administration increased the blood calcium and also increased the calcium excretion.

Reaction of Chronic Nephrosis to Thyroid and Parathyroid Medication

Dr. J. C. Meakins, Montreal: We have noted improvement in nephrosis as a response to thyroid and parathyroid medication. The effect is due to the readjustment of the calcium metabolism. A woman with recurrent attacks of edema, which was resistant to diuretics, was put on parathyroid medication with good results. The urine contained casts and red cells. The urea was normal. The blood calcium was low. On parathyroid extract, 50 units a day, there was a prompt increase in serum calcium, marked increase in urine output and drop in weight. When the parathyroid was stopped, the edema returned. In case of edema and ascites, and a reverse of the albumin globulin ratio, there was an increase in blood cholesterin, the blood calcium being low. There was no response until the eighth day, when the patient responded to thyroid. This was a case of mixed glomerular nephritis with nephrosis. In another case, in which there was edema, the parathyroid had no effect on the weight. With high protein diet there was response in weight, but none in the plasma protein. A drop in weight followed thyroid medication. The cholesterin in the blood dropped. There is evidently an endocrine imbalance in these cases which varies in different patients; sometimes thyroid is effective, sometimes parathyroid. Sometimes it is not due to calcium disturbance. The plasma proteins may not be changed. We must look elsewhere than the colloids of the blood for explanation of an edema which is refractory.

DISCUSSION

Dr. L. G. Rowntree, Rochester, Minn.: The increase in calcium under thyroid administration is very clearly shown. In two instances of parathyroid tetany, the symptoms disappeared under parathyroid administration. We felt that parathyroid extract was a real contribution to recovery.

Evaluation of Various Agents in the Reduction of Obesity

Dr. Solomon Strouse, Chicago: We have been unable to get any specific results in our cases. The women showed pictures suggesting disturbance of the thyroid, pituitary or ovary, but we were unable to obtain any definite clinical picture. One difficulty is the difference in the potency of the extracts and the short periods of time in which it was possible to make studies. We planned to make an experimental clinical study, using diet and administration of substances, and also control periods. Special attention was paid to family history and to changes in the menstrual cycle. Sella turcica pictures were taken. A diet of 1,200 calories was chosen. The subjects were numbered, and one group given thyroid, one pituitary, and one controlled by diet alone. The gland substances were carefully prepared. They were given for fourteen days, and if there was any influence on the weight curve the substances were continued. Most subjects lost weight on a 1,200 calory diet. Thyroid administration accelerated the weight loss.

Body Temperature

Dr. Elmer H. Funk, Philadelphia: Readings of continuous rectal temperatures were made in fifty tuberculosis patients, the thermometer being left in situ in such a manner as not to distress the patient, and the temperature recorded on a moving graph every thirty seconds. This study showed that many important variations of temperature, indicating activity of disease, are missed in individual patients through following the routine method of taking morning and evening temperatures.

Therapeutic Use of Oxygen

Dr. Carl A. L. Binger, New York: A low oxygen saturation of the blood may result in symptoms more or less serious, usually referred to the central nervous system, but also affecting the cardiorespiratory system and the whole organism. At an altitude of 12,000 feet there is a slight reduction of the oxygen saturation, from 96 to 84, yet people can have very severe symptoms from such a deprivation: headache, nausea, cyanosis, precordial pain, elevation of temperature, resulting from only a slight reduction of the normal percentage saturation. The anoxemia in clinical conditions is greater than that seen at high altitudes. With proper administration of oxygen, symptoms can be relieved and a catastrophe prevented. By treatment in the modern oxygen chamber the arterial saturation of oxygen can be restored to its normal level. In pneumonia, patients have to be kept in an atmosphere of about twice the normal oxygen content. Unless the alveolar oxygen content is increased to about 40 per cent, the oxygen deficit is not overcome. If the oxygen is raised too high, a new group of symptoms is encountered. About 60 per cent plus oxygen saturation is about the upper limit of safety.

Chamber Treatment of Anoxemia: Effect on Body Temperature

Dr. W. M. Boothby, Rochester, Minn.: The results obtained by us seem to have justified the expense of equipment and use of the oxygen chamber. The immediate clinical effect noted is lowering of temperature and pulse rate. Cyanosis causes elevation of temperature in addition to that caused by infection. The patient passes from alarming symptoms to a condition of safety. If removed too soon, the patient dies. The oxygen chamber treatment is reserved for acute cases. The cyanosis seen in chronic cases and in debilitated persons has been excluded, because treatment is not economically expedient. Not all patients survive. Of seventy-one patients treated, thirty-two lived. Twelve patients undoubtedly owe recovery to the use of the oxygen chamber. There was no evidence that any one was injured. The patient must be kept in the oxygen chamber until all signs of cyanosis have disappeared, and treatment should be commenced at the very first signs of cyanosis, in order to be most effective.

DISCUSSION

Dr. J. H. Means, Boston: The difficulty in the past has been due to the ineffective application of this agent. The old time method of applying oxygen with a funnel was simply a waste of oxygen and of hospital funds. I suppose that one cannot even now say that these observations prove that oxygen decreases mortality in pneumonia. That may never be proved, but I think that the clinical experience shown is sufficiently convincing evidence to make us want to have oxygen at our disposal for treatment, not only of pneumonia, but in other disease producing severe anoxemia. The type of apparatus used at the Rockefeller Institute, and also at the Mayo Clinic, would be prohibitive for most institutions. The tent seems to be ingenious and satisfactory.

Dr. J. W. Meakins, Montreal: The necessity of using oxygen early in the disease seems evident. The reason oxygen therapy fell into disfavor is that it was not used soon enough or intensively enough. With sufficient oxygen to remove the anoxemia, the piling up of lactic acid into the blood disappears.

Geographic Distribution of Goiter

Dr. W. J. Kerr, San Francisco: During the war I had the opportunity to study goiter incidence in a region covering one third of the United States; namely, Minnesota, the two Dakotas, Montana, Wyoming, Utah, Idaho, Washington, Oregon, Nevada and California. Examinations were made on 21,000 recruits at Camp Lewis, Wash., the ages ranging from 21 to 31 years. In general, the northern tier of states have the highest incidence, and correspond roughly with the map published by the U. S. War Department. Figures of the War Department indicate that exophthalmic goiter is most prevalent in regions of high incidence of endemic goiter. This is contrary to the generally accepted opinion that the frequency of one varies inversely with the frequency of the other. I believe that the army statistics are subject to error in view of the lack of knowledge of classification of goiter among the medical profession in 1917-1918. Many cases of large toxic goiter, without eye signs, were probably classed as exophthalmic goiter.

Epilepsia Tarda

Drs. David Riesman and Thomas Fitzhugh, Philadelphia: Epilepsia tarda is caused by a periodic insufficiency in the cerebral circulation the background for which may be anatomic, arteriosclerotic, hypertensive, due to endocrine dysfunction, or cardiac, including Adams-Stokes disease. The groups are not sharply defined but merge into one another.

Microscopic Examination of the Tonsil in Cases of Rheumatic Fever

Dr. W. W. G. MacLachlan, Pittsburgh: The clinical observations have been correlated with the pathologic observations in tonsillar lesions. Prolonged infection is associated with greater pathologic changes. This study includes the capsular and peritonsillar tissues of the tonsils. There is an unusual amount of peritonsillar fibrosis noted. The lesions found were: endothelial proliferation of the capsular cells; granulomatous-like reactions; lymph and plasma cell infiltration; bone and cartilage; foreign body giant cells; changes in the connective tissue of the capsule and in the appearance of collogen. In choosing controls for this work we must select carefully to exclude cases of rheumatic fever. As yet we cannot state definitely that the endothelial reaction is a specific change.

Chemical and Mechanical Factors in Experimentally Produced Peptic Ulcer

Dr. Frank C. Mann, Philadelphia: Dr. Williamson and I made some studies on a method for producing experimentally gastric ulcer in dogs, identical with that in man, which would heal with characteristic processes. In this way we could follow the onset, duration and healing process of the ulcer. In our studies we have emphasized two points: first, the chemical and mechanical factors in the production of the ulcer, and, second, the healing process which is related to the treatment by surgical and medical men and is also related to chemical and mechanical factors. The site of the lesion is due to its relation in regard to the outflow of gastric contents. It is quite possible that in hemorrhages granulation tissue is swept out of the healing process.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *The Journal* in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Gallop Rhythm. E. Holt, New York.—p. 453.

Angina Pectoris Combined with Severe Anemia.—Herrick has now seen seven such cases. Four were reported in 1918. Of the remaining three patients, all men, one had a typical pernicious anemia and an angina of effort; the second, aged 70 and nonsyphilitic, showed evidence of vascular and myocardial degeneration, as indicated by dyspnea, often nocturnal, numerous extrasystoles and characteristic substernal pains on walking. After more than a year of annoying cardiovascular disturbance, a severe anemia became manifest. This had the characteristics of pernicious anemia, and was the immediate cause of death. The anginal manifestations lessened as he was confined to the house and finally became bedridden. The third patient, aged 63, complained of marked hematuria of more than one year's duration, pain in the right lumbar region, pallor, emaciation, dyspnea and weakness. Also, for one year there had been pain in the chest on walking. At first this pain appeared only on walking a long distance. Gradually, the amount of effort necessary to bring on the pain lessened until walking 30 feet, or even moving about the room, would bring it on. The pain often began in the left arm, and then passed to the chest. It was so severe in the sternal region that it forced him to stand still. He felt sure that death would have followed a continuance of walking. In the past history there was nothing of moment except that since 1920 he had occasionally had attacks of vertigo of the Ménière type, some of them quite severe. There was no history of syphilis. As a result of an extended study of the case, including pyelography and microscopic examination of a gland cut out from the neck, a diagnosis was made of carcinoma of the right kidney with metastases, gallstones, Ménière's disease, severe secondary anemia, arteriosclerosis and angina pectoris. Autopsy showed carcinoma of the right kidney, metastases in the liver, lung and glands, gallstones, and marked senile arteriosclerosis of the aorta and coronary arteries. The left coronary was sclerosed and solid from its mouth to its division into the left anterior and descending branches. Both these branches had calcified plaques. The muscle of the heart showed fatty infiltration with areas of fibrosis.

Disturbed Cardiac Mechanism in Subacute Bacterial Endocarditis.—The rhythm of the heart was investigated by Rothschild et al. in 123 cases of subacute bacterial endocarditis, 109 of which were in the active or bacterial phase of the disease, and fourteen in the bacteria-free or healed stage. Auricular fibrillation was encountered only once among the active group, an incidence of less than 1 per cent, and in this case the rhythm had been normal until three days before death. In three other cases in which fibrillation was noted, and in the single instance of flutter, the endocarditis had already progressed to the bacteria-free stage. These observations demonstrate how exceptional auricular fibrillation is in the active or bacteria period of the disease. On the other hand, this irregularity is observed in the bacteria-free stage with perhaps the same frequency as in chronic rheumatic valvular disease. Observations on a large series of patients with fibrillation have convinced the authors that once this arrhythmia is permanently established, there is little danger that subacute bacterial endocarditis will supervene. The observation that auricular fibrillation and active subacute bacterial endocarditis are mutually exclusive (save in an exceptional instance) is of diagnostic value. The heart was involved in sixty-one of the sixty-five cases of rheumatic fever investigated. The electrical changes were found to vary within wide limits during relatively short periods of time and in most instances disappeared. Though these changes were usually transient, it is not as yet known whether their presence denotes that the heart has suffered permanent injury. These observations are of importance, first, because they demonstrate that the myocardium is implicated in some way in almost every case of rheumatic fever, and, secondly, because the electrocardiographic signs furnish a means of detecting cardiac invasion when other signs are wanting. Judiciously correlated with the general clinical study, these electrical changes will be found to be of diagnostic value.

Modes of Infection in Rheumatic Fever.—The belief is current that, as a rule, children, sick in hospitals with rheumatic heart disease, are not retained as institutional patients for periods long enough to insure their complete recovery. With this point in view, Boas and Schwartz studied the records of fifty-three children with rheumatic heart disease, who had been hospitalized. The importance of the lung as a source of reactivation or as a portal of entry of rheumatic infection was apparent, and at times a close connection exists between bronchopneumonia and rheumatic carditis. It is important to regard rheumatic fever as a generalized systemic infection of great chronicity; hence, attention should not be directed too exclusively to one organ, such as the heart or the tonsils. The tonsils play a relatively minor rôle as sources of reinfection. It is evident that present methods for after-care of children with rheumatic heart disease are inadequate. The ordinary form of prolonged general hospital care is harmful. The problem of the rheumatic child can be met only by providing some form of extended sanatorium treatment in an effort completely to eradicate the rheumatic virus from the infected individual.

Heart Disease and Public Health.—Cohn shows that from the point of view of the public health, the problem of heart disease is not simple as was that of tuberculosis, but is manifold. It includes disability from infectious diseases, such as rheumatic fever and syphilis, and disability incident to the process of aging. The effort to relieve rheumatic fever by removing areas of infection still wants prosecuting before a judgment on its value can be given. To prevent the onset of the disease is still impossible. The disabilities dependent solely on age, the major aspect of the problem, must elude approach on the side of etiology; to provide relief from distress must be the direction in which to expend effort. The infectious aspect of heart disease is, relatively speaking, small —smaller than is often thought—but the rate of so-called chronic heart disease is high and is constantly mounting. The rise may be alarming but it is not malign.

Roentgen-Ray Signs of Pulmonic Insufficiency. — The roentgen-ray examination made by Schwartz of three cases of mitral stenosis accompanied by the murmur of pulmonic insufficiency revealed dilatation of the pulmonary artery in all positions. The particular type of dilatation of the pulmonary artery in mitral stenosis was found in all cases presenting the Graham-Steell murmur. The lower voltage of the electrocardiograms showing right ventricular predominance and a smaller size of the T waves helps to differentiate these cases from congenital lesions of the heart. In combined cases of mitral stenosis in which aortic and pulmonic insufficiency is suspected, radiographic and electrocardiographic examinations are of value in eliminating the aortic lesions The characteristic roentgen-ray picture and the electrocardiograph are of great help in the diagnosis

Auricular Fibrillation in Abdominal Diseases—Felberbaum and Finesilver have observed clinically and electrocardiographically six cases of auricular fibrillation occurring in diseases of the gallbladder, acute appendicitis, gastric ulcer during the stage of recurrence and, finally, in a case of extensive postoperative intra abdominal adhesions The paroxysms of auricular fibrillation occurred only during the acute stages of the abdominal disorders The attacks were probably induced by a toxemia arising in septic foci within the abdomen Removal of the diseased organ is likely to be followed by a permanent disappearance of the arrhythmia Quinidine is occasionally valuable In some patients it may induce untoward results and may prove dangerous It is suggested that masked infections are possibly the etiologic factors for many cases of auricular fibrillation occurring in apparently healthy individuals

Cardiac Asthma.—Kahn attempts to distinguish the various forms of respiratory distress that occur in the course of heart disease, and to elucidate each form by carefully studied cases There is presented also a condensed review of the literature, and a clinical classification of the respiratory manifestations in heart disease, based on their pathogenesis

Recovery from Coronary Thrombosis—Pardee's patient, a man, aged 38 had a thrombosis of a coronary branch in January, 1924 The clinical history is typical, and the electrocardiogram furnished additional proof of a definite lesion of the heart muscle It is interesting that after this lesion he has been able to make a recovery to nearly a normal state It is particularly interesting that he has neither precordial pain on exertion nor unusual shortness of breath

Auricular Flutter with Heart Block—The case of auricular flutter with established complete heart block reported by Willius is the only case among 168 of auricular flutter occurring in the routine electrocardiographic examinations of 40,000 patients It is of interest that the patient is able to be reasonably active with such marked disturbance of cardiac action

Treatment of Acid and Alkali Burns—Experiments made by Davidson indicate that the treatment of acid and alkali burns by washing the burnt area thoroughly with plain water is superior to neutralization When treatment by neutralization is employed, it should be used only after the maximal amount of the caustic has been removed by thorough washing

Treatment of Burns—Goldblatt combats shock, and sterilizes the burn with tincture of iodine, one-half strength, followed by the application of a dressing wet with sterile solution of sodium bicarbonate, 10 per cent The dressing is made of loose fluffs of gauze, in the folds of which several small, soft, rubber tubes, of the Carrel type, or plain tubes with fenestrations in them, are incorporated and are allowed to protrude beyond the bandage This allows of easy saturation of the dressing, periodically, without removal of the bandages or the flooding of the bed This dressing is maintained for from twenty-four to forty-eight hours, by which time the shock, if present at the beginning, will either have entirely disappeared or become greatly ameliorated The dressing is then completely changed by soaking, and a new dressing of similar type is applied and kept on for two or three days longer, by which time the acute inflammatory character of the wound changes to the milder appearance of the second or secretory stage All dressings are now removed, the blisters are opened aseptically, and the burn is exposed to sunlight during the day This is done by exposing the wound to the direct sunlight, beginning with five minutes every two hours and increasing to twenty minutes, and in the intervals, to the air If sunlight is not available, ordinary electric lights may be used At night, a wet dressing of sodium bicarbonate solution is applied Continued use of alkaline dressings is employed to soften the crusts which form because of the air exposure, and to check the process of autolysis going on in the burned tissue

Intradermal Salt Solution Test.—There is frequently a reduced disappearance time of the intradermal salt solution wheal after operation Appel and Brill have suggested this test as a method for determining the need of the tissues for water after operation

Results of Surgery of Biliary Tract—An analysis has been made of 136 cases of gallbladder disease, of which 94 + per cent have been followed by Eliason and Ferguson A theory is advanced against the infectious origin of cholelithiasis Of the patients with acute cholecystitis, 89 per cent have been cured by cholecystectomy, with an operative mortality of 10 per cent, 76 4 per cent have been relieved of all symptoms by cholecystostomy, with an operative mortality of 4 3 per cent, combined, 6 per cent In the cases of chronic cholecystitis, 87 5 per cent of the patients on whom a cholecystectomy was performed were cured, with an operative mortality of 4 1 per cent, cholecystostomy did not result in any mortality, and 72 per cent of the patients were relieved, combined, 2 5 per cent The operative mortality of the combined acute and chronic infections of the gallbladder, unassociated with other lesions, was 3.6 per cent. Of the patients operated on for biliary obstruction, 77 per cent were relieved. The operative mortality was 23 per cent.

Blood Calcium and Hypertension in Pregnancy.—Stieglitz reports the results obtained in 222 blood calcium determinations from a series of cases, including normal pregnant women, pregnant women with hypertension, and some nonpregnant controls. He says that hypocalcemia is not of major etiologic significance in arterial hypertension in pregnancy, despite the fact that in such cases the relationship should be most conspicuous. During the final month of pregnancy a gradual rise in arterial tension is associated with a moderate hypocalcemia. Immediately after parturition a fall in blood pressure occurs, with a corresponding rise in the blood calcium concentration. Coincident and probably associated with the onset of lactation, a secondary elevation in arterial tension occurs, with a corresponding and equally transient hypocalcemia. The latter phenomenon permits of physiologic interpretation.

Effect of Breathing Dry Air on Vital Capacity.—An experimental method is described by Leas for testing the effect on vital capacity of breathing dry air. One hundred patients, normal as to heart and lungs, were tested. The average increase of vital capacity in these cases was 12.5 cc., or 0.3 per cent. A number of patients with cardiac decompensation were tested; there was an average increase of 190 cc., or 11.4 per cent. In patients with cardiac compensation there was an average increase of only 35 cc., or 1.3 per cent. Patients with asthma varied in their response. Several responded with an increase before and after the injection of epinephrine hydrochloride. Others responded with an increase due to the dry air and not to the epinephrine hydrochloride; the response in others was just the reverse. The conclusion seems justified that the breathing of dry air extracts enough of the moisture to increase temporarily the vital capacity in the majority of patients with bronchiolar edema, decrease the lung volume and the number of râles, and produce a sense of subjective relief. However, if the vital capacity is reduced because of bronchial obstruction other than moisture, interstitial pulmonary edema or a rigid lung due to stasis, breathing dry air does not cause any change. The procedure may also be used to differentiate between those patients with asthma whose bronchial obstruction is due chiefly to moisture and not to hypertonus or hives, and thus will be a means of selecting those patients who will improve, in all probability, in a dryer climate.

Effect of Intravenous Injection of Strophanthin.—Wyckoff and Goldring gave 248 intravenous injections of strophanthin to thirty-two patients who had heart failure, without fatalities or harmful effects. A definite cardiac effect was noted after 163 injections. The initial effect was noted in from five to twenty minutes, and the maximum effect in from fifteen to fifty minutes; as a rule, the larger the dose, the earlier the initial effect and the more delayed the maximum effect. A greater amount of strophanthin was necessary to reduce the ventricular rate in patients who had auricular fibrillation with elevation of temperature than in those without elevation of temperature. The variation in dosage was less when calculated on the basis of body weight than on the basis of total dosage. The persistence of action of the drug was variable in the cases observed, but in all except three the persistence was never longer than five days. Mild toxic symptoms were noted in three of fifty-two instances in which full therapeutic effects were obtained. It would seem that strophanthin, if given in fractional doses, may be administered with safety intravenously to patients with auricular fibrillation who have not received digitalis recently. When strophanthin is given to patients with regular sinus rhythm, greater care must be used. In these patients, clinical improvement seems to be the only criterion for full therapeutic effect; and since moribund patients may not show clinical improvement, there is greater danger of overdosage.

House Dust as Cause of Asthma and Hay-Fever.—Rowe has tested 160 new patients with asthma with stock house dust solutions; 42 per cent gave reactions and twenty patients with perennial hay-fever also gave such reactions. Dust reactions have been obtained in all age groups with the scratch test. A large number of patients gave a characteristic history of dust sensitization. The necessity of testing with a large number of stock and autogenous dust extracts is demonstrated. The data collected show that reactions to dust rarely occur without one or more other reactions to proteins commonly used in testing. Desensitization to house dust extracts which give definite reactions in the patient is said to be advisable in cases in which a marked history of dust sensitization is present.

Histamine Test of Gastric Function.—Bockus and Bank do not believe that the injection of histamine with or without a water meal is in any way comparable to the fractional gastric analysis as a general test for gastric function. They believe with Rehfus that the fractional method yields information as to gastric work, and that a definite load must be imposed on the stomach in order to judge its ability to perform its function. The normal physiologic load is food, and that substance must be used in order to get the maximum information concerning the secretory and motor function. The performance of the ordinary fractional gastric analysis and the histamine gastric analysis will yield more information than either alone in stomachs with a low acidity. Both tests should be made in such cases.

Iodine Medication of Hyperthyroidism.—According to Starr the course of hyperthyroidism under iodine medication is characterized by remission and recurrence during the administration of iodine and by a reaction, which may be extreme, after the iodine is discontinued; hence, the prolonged treatment of patients who have hyperthyroidism with iodine in dosage sufficient to produce these effects is without final benefit.

Chronic Acidosis and Kidney Changes.—Seegal gave rabbits varying doses of tenth-normal hydrochloric acid and ammonium chloride over periods of time extending from eleven days to one year. The plasma carbon dioxide capacity was lowered, and the animals excreted an acid urine. Casts and albumin were obtained constantly throughout the experimental period. At autopsy, however, the only demonstrable pathologic change in the kidney was acute degeneration of the convoluted tubules, similar to cloudy swelling, but also accompanied by marked pyknosis of the nuclei in cases of longer duration. When the giving of acid-forming substances was stopped, the kidney promptly returned to normal. The results with dogs were comparable, except that a greater dose of chloride had to be given in order to produce an acidosis, and there was less albumin and casts. The possible causal relation of acidosis to orthostatic albuminuria following strenuous exercise is discussed.

Hemorrhagic Focal Gastroduodenal Lesions.—Three cases are reported by Rivers as typical illustrations of one group of patients in whom infectious lesions are probably responsible for gastro-enteric hemorrhages. They are additionally interesting and important because they stimulate speculation as possible forerunners of chronic ulcer. Rivers is of the opinion that many of these cases of so-called appendiceal bleeding or gallbladder bleeding are probably caused by acute lesions in the stomach or about or in the duodenum.

Involvement of Nervous System in Hodgkin's Disease.—In ten of thirty-six patients with Hodgkin's disease seen by Ginsberg, definite invasion of the nervous system was a striking clinical phenomenon. In one case, persistent pruritus was the only symptom present for one year before the advent of the constitutional symptoms of asthenia, fatigability and dyspnea on exertion In the second case, a diagnosis of a primary spinal cord neoplasm was made. The third case suggested a traumatic spondylitis and later a transverse myelitis. In the fourth case, extensive lesions in the osseous system gave rise to pain in the shoulder and in the thigh two and one-half years before the superficial cervical lymph nodes became enlarged Another patient had simultaneous itching in the feet extending to the knees.

Nucleic Acid in Tea Leaves.—It seems very probable to Calvery that the nucleic acid, which is characterized by the presence of a pentose, is a naturally occurring product in tea leaves.

Vitamins in String Beans and Green Peppers.—Quinn, Burtis and Milner assert that both the string beans and the green peppers contain vitamin A in about the same concentration as has been found for lettuce, more than for cabbage, but considerably less than for spinach. The vitamin B concentration of about 0 3 units per gram indicated that both string beans and green peppers are as good sources of this vitamin as lettuce or cabbage but not as good as spinach Green peppers were found to contain at least four times as much vitamin C as string beans, or about 1 unit per gram. This concentration is comparable with the highest which has been reported for any plant material, such as the raw leaf tissue of cabbage or spinach or the juice of orange or lemon

Fate of Sugar in' Animal Body.—The Coris conclude that ketosis is associated with a reduced functional atcivity of the pancreas, and in consequence of this, with a reduced capacity of the tissues to oxidize glucose.

Study of Bile Pigments.—It is shown by von Oettingen and Sollmann that the deep blue-green produced by adding mercuric chloride to bile (for instance, the Schmidt test for bilirubin in the feces) is not due to biliverdin but to a mixture of green and blue oxidized bilirubin which exists as the mercury salt

Indophenol Test.—A test for phenols, depending on the quinonechloroimide reaction producing indophenols, is described by Gibbs. The test is delicate, both qualitatively and quantitatively, to one part of phenol in twenty million by ordinary manipulative skill. A method for the preparation of the reagent is given and the solubility of the best reagent, 2,6-dibromoquinonechloroimide, has been determined with considerable accuracy.

Fish Synthetize Vitamin D.—It is suggested by Bills that the substance, or group of substances, known as vitamin D may be synthesized by fish.

Specificity of Weil-Felix Reaction in Brill's Disease.—Havens states that the results obtained in Alabama with the macroscopic Weil-Felix test in more than 100 cases of Brill's disease indicate that the reaction is elicited in about 95 per cent of cases during the second week or later. It is usually negative during the first week, becoming increasingly stronger until convalescence. Tests including more than 1,000 negative results demonstrate its specificity. Agglutination of *B. proteus* X19 in dilutions higher than 1:80 has not been obtained in other disease conditions. The microscopic Weil-Felix test with dried blood has yielded false positive results and, for this reason, is regarded as being of doubtful value. The agglutinins for *B. proteus* X19 in serums from patients with Brill's disease and also in serums from rabbits after the injection of guinea-pig brain virus are relatively thermolabile; they are destroyed by heating the serum at 62 C. for one hour.

Influence of Infection on Development of Scurvy.—Six of eleven infected guinea-pigs placed on a scurvy diet by Jaffe developed severe purulent infections and did not develop scurvy within from nineteen to forty days. Uninfected guinea-pigs on the same diet developed scurvy in from thirteen to eighteen days. The injection of *Staphylococcus albus* into animals with early signs of scurvy caused a rapid fatal termination. The course of scurvy was not influenced by the injection of standard staphylococcus vaccine. These studies suggest the possibility that antiscorbutic substances may be developed by bacterial growth in the tissues, or as a result of the action of absorbed toxins on the internal organs.

Diagnosis of Pulmonary Tuberculosis.—Schwartz has analyzed 150 cases, of which 68 per cent occurred in the third and fourth decades of life. Twenty-six per cent of the patients gave a family history of the disease; 42 per cent had influenza, 16 per cent pleurisy, and 13.3 per cent pneumonia; 26.7 per cent had unilateral and 73.3 per cent bilateral involvement; 43.3 per cent of the patients were well nourished. The most frequent symptoms are enumerated, and the importance of careful history taking is stressed.

Drying Up Lactating Breasts.—To dry up lactating breasts, Larkin recommends the use of the AC or Bender bandages. He has found them to be far superior to the usual inelastic sheeting or muslin bandages formerly employed.

Hereditary Woolly Nevus of Scalp.—Wise reports two instances of a congenital anomaly of the scalp hair of two unrelated children. In the first case, a child of Jewish parentage and a native of New York, there was an associated nevus pigmentosus linearis of the neck and arm; in the second, a child born in Syria and of Syrian parentage, the birthmark was confined to the hair. In neither case was there any sign of pigmentation (or depigmentation) of the scalp from which sprang the anomalous growth of hair. The scalps in both children appeared to be entirely normal. In the first case, the right parietal and entire occipital portions of the scalp were covered by a dense growth, over a uniform area, of fine, golden brown, extremely soft and silky hair, which, to the stroking hand, imparted a distinctly "woolly" sensation. The margins of the area covered by abnormal hair were rather sharply defined, but blended with the margins of the adjacent normal hair without showing lines of demarcation; nor was there a gradual admixture of normal and abnormal hair at the borders of the affected areas. In the birthmark area there were no normal hairs. The scalp itself was entirely normal. The back of the neck, a little to the right of the midline, and extending from the hairline down to the first dorsal vertebra, was the seat of a slightly roughened, dark brown, striated, linear, pigmentary nevus, appearing in the form of three parallel narrow bands. On the right elbow and wrist there were several similar formations, with faint evidences of connecting linear bands between the neck and wrist lesions. The upper portion of the pigmented striae blended with the hair nevus at the nape of the neck. In the second case, the entire top of the scalp, from the frontal hair line to the back of the scalp and extending down the back of the scalp to a line approximately at the level of the tops of the ears, and the parietal portions of the head, presented a heavy growth of light brown, soft, kinky, fine textured hair of a decided woolly feel. There was a sharp line of demarcation between the normal hair and the birthmark hair, and there was no blending of the two. The scalp appeared normal.

*Acute Local Infection Treated by Heat and Radiant Energy F de Kraft and others New York —p 176
*Effect of Mechanical Vibration on Spinal Reflexes M L H A Snow and others New York —p 188

Diathermy Treatment of Multiple Sclerosis —Stephenson reports five cases of multiple sclerosis that he treated by diathermy In two of the cases, during the course of treatment there were distinct evidences of exaggeration of symptoms referable to morbid changes within the cranial cavity, without evidence of an increase of the symptoms referable to spinal cord involvement Stephenson believes that this argues strongly for at least a control of the spin l cord disease bv diathermy

Heat Treatment of Local Infections —Certain local infections may become virulent in type, spreading rapidly and endangering life In cases of this extreme type, de Kraft et al assert that prompt utilization of various rays of the spectrum—high degree dry heat, radiant light and heat, diathermy, ultraviolet rays and roentgen rays—has proved effective

Effect of Mechanical Vibration on Spinal Reflexes.—According to Snow and others, mechanical vibration induces reflex effects through spinal vibration It stimulates or inhibits according to the strength and the length of treatment, and so induces a reflex of contraction or of dilatation over a specific site It stimulates relaxed muscles and relieves muscular tension, as the effect of spinal vibration It may raise or lower blood pressure if uncomplicated, when applied at respective regions Mechanical vibration induces visceral reflex effects, as of contraction or dilatation demonstrable by percussion over specific spinal areas for the heart, lungs, liver, spleen and stomach

Constitutional Anomalies of Epileptic Persons —Clark contends that the nature and degree of the epileptic attack portray the depth of regression even to that of metro-erotism, as seen in the deepest states of coma There does not exist a constant physical substrate for the epileptic constitution That is, no essential alteration is shown that is not seen in an equal number of other individuals who are, perhaps, biologically inferior either as a result of their inheritance or because of the continued activity of their disease phenomena Just what part is due to the latter, and what proportion may be ascribed to the fundamental constitutional inheritance, are matters concerning which anthropologic data as yet offer no line of demarcation If one wished to take a broader psychoanalytic view, one might say that organic anomalies pave the way to inferiority of mechanism, or that many of the defects present are, at least so far as functioning is concerned, somatic manifestations of narcistic defect colligative of those known to exist in the psychic constitution of epileptic narcism

Training Idiot and Imbecile.—Veith asserts that, contrary to current belief the idiot and the imbecile can be trained to perform quite difficult tasks They are capable of making only a few associations of the most simple nature, and those resulting from identical experiences Thus, their training involves not only laborious but continuous effort in taking them away from their world of inferiority and giving them greater contact with their outside world

Carbohydrate Metabolism of Feebleminded. — Bronfenbrenner has found that the metabolic mechanism of mental defectives is impaired to some extent Their impairment has been shown by their peculiar handling of certain substances which are derived from both food and the disintegration products of bodily cells, and which are the source for the after-hydrolysis fraction of urinary reducing substances The high carbohydrate diet, resulting in an increased quantity of glucose circulating within the metabolic channels, appears to compensate for the impairment Therefore, the customary high carbohydrate diet of institutions for feebleminded is to be regarded not as a matter of a chance or of administrative economy, but as an automatically established way of meeting the metabolic peculiarity of the kind of patients cared for Inflammation is always accompanied by increased disintegration of body cells, which raises the demand for metabolic efficiency Therefore, the administration of dextrose in cases with retarded healing might be of therapeutic value because it induces an adequate handling of the products of cell disintegration This conception has been checked up on two clinical cases with promising results

Hydatid Cysts of Liver.—Mills analyzes sixty-three cases, thirty-nine of which were seen in California. Thirty-seven cases were treated by marsupialization and drainage. Recurrence was noted in two cases. One case was notable in that embolism of the brachial artery occurred as a sequel, embolectomy being performed.

Pyelovenous Backflow During Pyelography.—It is definitely stated by Hinman that the pyelovenous backflow frequently occurs at the time of pyelography, and that tubular backflow for a short distance into the papillary ducts also occurs.

Hemorrhagic Cysts of Kidney.—Two cases seen in the Mayo Clinic are reported by Judd and Simon, and thirteen others on record are analyzed.

End-Results in Breast Cancer.—Statistics quoted by Schreiner and Stenstrom show definitely that results in operable cases are best obtained by radical operation followed by irradiation, although in some instances, irradiation alone has proved of curative value. In the hopeless, inoperable cases of breast cancer, radium and roentgen-ray treatment has made the remaining days of the patient more comfortable.

Effects of Thyroidectomy and Thyroid Feeding on Cardiac Output.—The effects of thyroidectomy and of the administration of thyroid substance on the cardiac output of dogs have been studied. The following results have been obtained by Blalock and Harrison: The cardiac output is increased in hyperthyroidism and decreased in hypothyroidism. The change in cardiac output is usually somewhat greater than the change in metabolic rate. The administration of iodine to animals receiving thyroid substance is followed by a marked decrease in cardiac output, as well as in metabolic rate. This decrease continues for from six to ten days, after which the cardiac output and metabolic rate increase rapidly. The metabolic rate and cardiac output remain elevated for two months or longer after the cessation of thyroid feeding. The former returns to normal before the latter. Digitalis decreases the output of the heart of dogs with hyperthyroidism, but this effect is somewhat less than the effect on the cardiac output of normal dogs. The oxygen pressure and carbon dioxide pressure may be important factors in the regulation of the cardiac output. Thyroid extract should be used with caution in myxedematous patients presenting evidence of cardiac weakness, and withheld when cardiac decompensation supervenes. Iodine therapy is valuable for a time in patients with hyperthyroidism, and especially so in patients with pronounced cardiac symptoms. The prolonged administration of iodine is probably useless. The administration of digitalis is indicated in hyperthyroidism.

Latent Postoperative Tetany.—Parathyroid injury after goiter operations was demonstrated by Richter and Zimmerman in 14 per cent of the cases. In most of these cases the tetany is purely "latent," and is not detected unless objective examination is made for the signs. Symptoms and signs are for the most part transitory, and probably represent mild, temporary disturbances in parathyroid function. Tetany may be controlled by changing the intestinal flora to one of the aciduric type, and by the administration of calcium by mouth. This regimen, which presumably prevents absorption of toxic materials liberated in the colon from proteolytic putrefaction, consists of a meat-free diet, liquids in large quantities, including at least 1 quart of milk daily, and lactose, from 200 to 300 Gm. in the twenty-four hours. The authors have used Collip's active principle of the parathyroid with very gratifying results. Its use is desirable in those cases in which clinical manifestations do not disappear within a relatively short period of time.

Prognosis of Endometrial Carcinoma.—Seventy cases of fundus carcinoma were studied by Lindsay. Adenoma malignum (twenty-three cases with two deaths) is of relatively low grade malignancy, and responds well to treatment. Preoperative irradiation and hysterectomy gave the best results (seven cases, no deaths), but the almost equally good results of irradiation alone (ten cases, one death) would seem to warrant its selection as the treatment of choice. Adenocarcinoma (thirty cases with twenty-one deaths) offers a very bad prognosis, and demands rigorous treatment from the outset. The best results were obtained by preoperative irradiation and hysterectomy, each of which alone was unsatisfactory. Suspicious cases of fundus carcinoma showed no mortality due to cancer, and appeared to be effectively controlled by irradiation alone. Adeno-acanthoma and adenomyocarcinomatosis have a high mortality and require the same treatment as adenocarcinoma. Embryonal carcinoma was present in two cases only, and the results are in conformity with the belief that better results are obtained in this class of case by irradiation alone than by operation.

Partial Gastrectomy for Cancer.—Partial gastrectomy was performed 120 times in the Mayo Clinic for malignant disease of the stomach and nine deaths resulted, a mortality of 7.5 per cent. Balfour describes the technic employed.

Splinting Vertebral Column in Pott's Disease.—Lange uses one splint made of rust proof steel placed on one side of the spinal column, with a celluloid splint on the other. These splints are fixed with thin steel wire of the rust proof variety instead of silk. The advantage of steel is that it has greater stability than celluloid. A 3 to 4 mm. steel splint would compare quite favorably in stability with a 10 mm. celluloid splint.

Use of Costal Cartilage in Plastic Surgery.—Kelly uses wood carvers' chisels to remove a piece of costal cartilage of any desired size and form. The cartilage may be removed much more easily, more rapidly, with less danger, and more accurately than can be done with the older methods of removal.

Ethylene-Oxygen Anesthesia.—Allen and Murray have found that ethylene-oxygen anesthesia is superior to every other type of anesthetic in every way. Postanesthetic pulmonary complications are rare. Postanesthetic nausea and vomiting occurred in 39.6 per cent of major cases. The cost of ethylene-oxygen anesthesia is about seven and one-half cents a minute.

Chemical Composition of Colostrum and Early Milk.—Lowenfeld et al studied the chemical composition of milk of the first fourteen days of lactation There appears to be a difference between the milk of primiparas and multiparas with regard to the behavior, in the early days of lactation, of the protein and fat. The protein and ash content of the milk vary regularly according to the day of lactation, being very high in primiparas, less so in multiparas, on the second and third days, and falling steeply during the first week to reach an approximately normal level The sugar content varies also according to the day of lactation, but inversely as the protein, and less regularly, being at its lowest in the early days and rising irregularly to a normal level by the end of the second week The fat content varies only according to the physical conditions of the breast and the actual extraction, and not in relation to the day after parturition, but in primiparas the general behavior is reversed in the first days of lactation The calcium content varies up to the fifteenth day among individual women, but not according to any factors concerned with individual lactation, and is uninfluenced by factors local to the breast. There is some possibility that the protein content of the milk rises slightly at the end of a single feed, the difference being greater when the samples are taken in relation to an actual feed than when only the first and last portions of an artificially emptied gland are considered. The lactose content of the milk appears to be higher at the beginning than at the end of a feed. The total solids vary roughly as the fat.

Estimating Blood Chlorides.—A simple and rapid method of estimating blood chlorides on 0.2 cc is described by Smirk. The principle of this method is the destruction of the organic matter of the blood by ammonium persulphate and concentrated nitric acid, with the usual precipitation of the chlorine as silver chloride by excess of silver nitrate. The excess is titrated against alcoholic ammonium thiocyanate solution, a concentrated solution of ferric alum being used as the indicator The titration is performed in the presence of acetone, which intensifies the end point by decreasing the dissociation of the ferric thiocyanate, and for a similar reason renders it more permanent. This enables a series of titrations to be brought to the same depth of red, which, with the sharpened gradation of the end-point coloration, permits accurate comparative observations to be made.

Estimation of Blood Iron.—A simple and rapid method for the accurate estimation of blood iron with the use of 0.2 cc. of blood is described by Smirk The method depends on a colorimetric comparison of the iron as ferric thiocyanate with an artificial color standard consisting of a mixture of cochineal, 4 cc ; methyl red, 3.2 cc, and hydrochloric acid, 4 cc, dissolved in an equal mixture of acetone and water To the approximate depth of color required, a final adjustment of tint is made by adding drops of methyl red if the orange tint predominates, and cochineal solution if the red is too clear. The color is permanent, and indistinguishable from that of the thiocyanate.

Recovery from Insulin Hypoglycemia.—No significant difference was observed by Kermack et al. in the time taken to recover from insulin hypoglycemia following intravenous dihydroxyacetone administration as compared with dextrose. Methylglyoxal and sodium pyruvate fail to cause animals to recover from insulin hypoglycemia and appear to have a toxic action Negative results were also obtained with sodium lactate, glycerin, sodium citrate and rhamnose.

Biochemistry of Aqueous Humor.—Duke-Elder asserts that from the biochemical point of view neither the normal nor the abnormal aqueous humor shows evidence of the existence of any special secretory mechanism in its elaboration, but appears to be rather a dialysate of the capillary blood.

Effect of Excessive Ultraviolet Irradiation.—Observations that were made by Leigh-Clare showed that provided the eyes were shielded, exposure of young growing rats to ultraviolet irradiation for periods up to thirty minutes daily was not found to have a deleterious effect on the growth and well being of the rats (although this dose was found to be fifteen times the adequate dose for male rats). It was also found that exposure for thirty minutes to the lamp had no more beneficial results than exposure for the shorter periods.

Antirachitic Value of Fresh Spinach.—The presence of vitamin D in small amounts in fresh spinach was demonstrated by Roscoe His experiments do not afford any evidence in favor of the theory that vitamin D, after synthesis in the leaf, is rapidly removed

Onset of Postencephalitic Parkinsonism. J. P. Steel —p 231.

Synthetic Thyroxine.—Last year, Harington and Barger succeeded in synthesizing a substance which corresponds in all particulars with thyroxine isolated from the normal gland This material has been tested by Lyon and Redhead for physiologic activity on two myxedematous subjects Striking changes followed the administration of the drug The metabolic rate rose immediately and rapidly, declining after the drug was discontinued The rise in the temperature and the pulse changes closely parallel the alterations in the basal metabolic rate Reduction in weight took place in both subjects Notable change in the blood pressure was not observed Diuresis and diarrhea were caused after each injection in one case The clinical improvement was striking

Seroprophylaxis of Measles.—The experience of Benson and Lawrie with the serum prophylaxis of measles has been very satisfactory Of twelve susceptible children exposed to infection with the measles virus, eleven escaped infection subsequent to passive immunization with convalescent measles serum, while one developed a highly modified form of the disease The eleven children who escaped infection received their prophylactic injection of serum on, or before, the fourth day of exposure The child who developed the extremely mild attack of measles did not receive the injection until the sixth day of exposure The serum was injected intramuscularly The dose was 10 cc Of nine nonimmunized children, in whom the conditions of contact with measles were, if anything, less intimate than in the foregoing group, two developed typical measles after a period of incubation varying from ten to fourteen days

Action of Ammonium Benzoate on Urine.—Clinically, Johnston found that ammonium benzoate produced or maintained an acid urine, and when the urine in *B coli* cystitis was acid, more relief to symptoms was procured by alkalizing with sodium bicarbonate before administering the benzoate Some alkaline cloudy urines rapidly became clear, with relief of symptoms, but in obstinate cases of chronic cystitis, especially in women, ammonium benzoate merely prepared the way for methenamine, the combination of these two drugs giving good results In treating cystitis with ammonium benzoate, the first effect is the production of a moderate degree of diuresis, which is maintained, and this, no doubt, plays a part by flushing the urinary passages That ammonium benzoate has an antiseptic action is doubtful, and the drug is certainly not to be relied on clinically when used alone To ascribe an antiseptic power to it because of its acidifying properties is fallacious, as the drug cannot produce a urine sufficiently acid to prohibit the growth of organisms Any effect must be due to the salts of unconjugated benzoic acid in the urine, a 5 to 8 per cent solution of which seemed capable of slightly retarding the growth of *B coli*

*Case of Rat Bite Fever T L Hardy and H M Savery—p 703
*Misdiagnosis in Case of Acute Intestinal Obstruction C E H Anson—p 704
*Relief of Migraine H C Rook—p 705

Rat Bite Fever—The case recorded by Hardy and Savery was unusual in that at no time were there signs of recurrent inflammation in the wound, which remained healed and painless throughout, nor was there enlargement of the lymph glands

Acute Intestinal Obstruction—In Anson s case the symptoms present led to a diagnosis of carcinoma of the rectum and as obstructive symptoms increased, a colostomy was performed A condition of diffuse carcinomatosis was found with small nodules over the small intestines and colon and also in the mesentery The patient died two months later A necropsy was performed The mass felt by rectum proved to be a secondary deposit situated between the rectum and the bladder The primary growth was situated in the cecum a typical adenocarcinoma with very well marked colloid degeneration A huge mass of secondary carcinoma was also found beneath the left lobe of the liver

Treatment of Migraine—The treatment employed by Rook consisted of giving from 2 to 4 drachms (7 5 to 15 cc) of a 50 per cent solution of magnesium sulphate one hour before rising, and following this, the patient was instructed to lie semiprone on the right side At the end of the hour, a large tumblerful of hot water or hot weak tea is taken This is most important, since if the salts are not evacuated within two or three hours, a feeling of intense depression is produced which may result in an attack The day or half-day previous to taking the salts is a starvation day, but this should be done not more often than once a week Certain articles of diet must be strictly limited These are fats of all sorts, and in certain cases eggs, also chocolate, cocoa, coffee and alcohol.

Effect of Administration of Parathyroid on Serum Calcium C P Stewart and G H Percival—p 349

Enumerating Premature Ventricular Beats—A method is described by Bourne for enumerating accurately, over long periods of time, the number of normal and of premature ventricular beats The effects of exercise, posture, amyl nitrite and atropine on the number of premature beats, and simultaneously on the heart rate, have been studied in a series of twenty-eight cases in which such premature beats were of reasonably frequent occurrence The curves taken from thirteen of these cases suggest reentry rather than parasystole as being a causative mechanism

Circulation Rate in Man—The data in 118 determinations on eighteen subjects are presented by Davies and Gilchrist The ethyl iodide method of estimating circulation rate is said to possess many advantages over methods hitherto in use Determinations can be carried out in a few minutes and do not produce discomfort or disturbance to the subject The results are reasonably consistent, provided constant conditions are maintained and errors of technic are avoided Excessive amounts of ethyl iodide appear to have a depressant effect on the circulation rate in certain individuals For this reason, repeated estimations over too short a period are liable to be fallacious In the present series of observations, there is no relationship between the circulation rate and any other physical measurements in different individuals Considerable variations in circulation rate may be associated with varying conditions of metabolism activity, environmental temperature, posture and emotional excitement For this reason, the conditions under which observations are made on any given subject must be carefully standardized that comparable results may be maintained

Fractional Analysis of Gastric Contents—A method of obtaining simultaneously samples of gastric contents at two points is described by Duthie, and the variations of the free acidity and total chlorides are compared in three cases Differences in the free acid and total chlorides were found in the upper and lower regions of the stomach during the digestive cycle in three cases Duodenal regurgitation was shown to affect the gastric contents chiefly in the lower part of the stomach.

Gastric Function in Arthritis.—Miller and Smith assert that the association of achlorhydria and hypochlorhydria with chronic arthritis is not so marked as to justify the conclusion that it is a primary factor in the etiology of the disease. In general, the frequency of abnormal gastric acidity approaches that found in a wide group of other diseases; it may be the result of depression of function due to debility and asthenia There is evidence that achlorhydria in chronic arthitis allows more ready multiplication in the bowel of streptococci, and may be, therefore, an accessory factor in the etiology of the disease

Effect of Mineral Acid on Acid-Base Regulation.—Dilute hydrochloric acid, in amounts corresponding to from 500 to 1,000 cc of tenth-normal acid a day, was given by Linder to four normal persons and to six patients with nephritis for periods of two to four days In the control cases a quantity of fixed base was available for excretion with the acid. This store was exhausted in two or three days, and its place was taken by ammonia, which was excreted in increasing amounts The extra base was derived from cellular and extracellular water. *In one mild case of chronic nephritis, similar results* were obtained The patients with chronic hydremic nephritis without gross edema showed an adequate response in ammonia formation, but the extra excretion of fixed base was lacking The azotemic patients showed diminished power to form extra ammonia This defect became greater as renal function failed In compensation there was a much greater excretion of fixed base, which in one case was derived entirely from cellular water The changes in the serum consisted of increases in the chloride and decreases in bicarbonate and p_H The total base usually decreased slightly. In the patients these changes were more extensive, giving evidence of failure to adjust the acid-base balance with the customary delicacy. In the two patients whose renal function was greatly impaired, severe acidosis was produced.

Heredity in Simple Goiter.—A series of six families is reported on by Bram, including among them twenty-six cases of simple goiter In two of these families cases occurred in four successive generations A second series of five families is reported, containing twelve cases of simple goiter associated with congenital deaf-mutism Evidence is brought forward in support of the view that hereditary predisposition is a factor in the etiology of simple goiter in some cases. The relation of predisposition and environment in such cases is discussed An explanation of the differences between the sexes in respect to the incidence and transmission of goiter is suggested The inheritance of goiter is considered in relation to mendelian laws It is concluded that simple goiter may be the manifestation of more than one abnormal hereditary factor, two of which can be distinguished by their behavior *in transmission*

Radium and Blood Cholesterol.—Brunton estimated the total cholesterol content of the blood and plasma of thirteen patients suffering from cancer. The average concentration was 149 mg per hundred cubic centimeters. In the oxalated plasmas of forty-four patients, the average concentration was 169 mg per hundred cubic centimeters. After operations for nonmalignant conditions, after treatment for malignant disease by diathermy, and after its treatment by radon, the plasma cholesterol may either increase or decrease. In thirty patients examined before and after treatment by radon, no relation was found between the alteration in cholesterol concentration, and either the dose of radon or the time of its action within the limit of seventy-two hours.

*Significance of Pulse Rate in Phthisis. J. R. Earp —p 314.
Binucleate Cells and Giant Cells in Tissue Cultures and Similarity of Latter to Giant Cells of Tuberculous Lesions. W. H. Lewis —p 317.

Experiment in Occupational Therapy.—McDougall describes a plan in effect at Wormly whereby an opportunity is given ex-patients to work for a livelihood under open air conditions and under medical supervision. Social activities first provided the funds. Now there is a newspaper, a store, wool farming and a pig farm to provide funds for the maintenance of this work.

Hemolytic Streptococci in Pulmonary Tuberculosis.—Of 119 patients suffering from pulmonary tuberculosis, twenty-two have been shown by Cumming to have hemolytic streptococci, indistinguishable from the ordinary hemolytic streptococci of surgical practice in the sputum. The occurrence of these organisms in the sputum has been shown to be related to a definite but limited extent with the incidence of hemoptysis and hectic fever and with the mortality. Possible lines of autogenous streptococcal vaccine therapy are discussed.

Significance of Pulse Rate in Phthisis.—Earp points out that whereas the minimum pulse rate (during the day) in tuberculosis is of no significance, the maximum pulse rate is of considerable significance. The range of pulse rate is even more significant than the maximum pulse rate.

Prevalence of Tuberculosis and Antituberculosis Campaign in Japan. R. Takano —p. 16.

Heredity of Blood Groups.—Furuhata, Ichida and Kishi classify human blood into three homozygotes of $\frac{ab}{ab}$, $\frac{Ab}{Ab}$, $\frac{aB}{aB}$ and three heterozygotes of $\frac{Ab}{ab}$, $\frac{aB}{ab}$, $\frac{Ab}{aB}$ The biochemical structures of human blood (iso-agglutinogen and iso-agglutinins) are said to be inherited by Mendel's law. A combination of one homozygote with another homozygote produces one kind of offspring. A combination of the same kind of homozygotes produces the same and pure type as parents. A combination of different types of homozygotes produces a hybrid. A combination of a homozygote and a heterozygote produces two types of offspring in the same proportions. In combination of heterozygotes of the same types, the grandparents and parents produce the offspring in the proportions of 1:2:1. Four types of children in the same proportion are born from a combination of heterozygotes of different types. Among 1,890 persons, representing 399 families, five cases were found that did not conform to the authors' theory.

7: 483-515 (Feb. 13) 1927

*Classification and Treatment of Tuberculids. J. Schaumann.—p. 483.
*Syphilis and Multiple Sclerosis. M. Molhant.—p. 498.

Classification and Treatment of Tuberculids.—Schaumann's paper is devoted to the study of tuberculids of tuberculous origin, and to that of paratuberculous lesions of the skin, such as lupus erythematosus, malignant lymphogranulomatosis, lupus pernio and multiple benign sacroids. Various methods of treatment are discussed. Finsen baths are useful. Gradually increasing doses of tuberculin injected into or beneath the skin are of great benefit. Tuberculin combined with neoarsphenamine appears to be the preferable therapeutic method. Good results were cited from intravenous injections of a gold preparation. Ten injections of graduated doses, from 0.01 to 0.1 Gm., are given, one a week. Of the author's twenty patients with lupus erythematosus thus treated, nine were cured, and ten improved. In one case, the treatment failed. Cure of a case of lupus pernio with large doses of sodium cacodylate was recently recorded.

Analogy Between Syphilis and Multiple Sclerosis.—Molhant emphasizes the resemblance between syphilis of the spinal cord and multiple sclerosis. It is evident, he says, in the clinical picture, in the serologic reaction and in the course of the two diseases. The efficacy of arsenical treatment in multiple sclerosis reenforces the analogy.

Mendelian Heredity of Tumors in Man. F. Miche.—p. 510.
Conjunctival Jaundice in Appendicitis. C. P. Caplesco.—p. 513.

Tuberculosis as Remote Sequela of Gas Poisoning During the War.—Achard's conclusions are based on personal clinical and roentgenologic observations and on those of other authors. Tuberculosis occurring recently in persons affected with gas poisoning during the war presents a chronic fibrous form. It follows respiratory disturbances appearing at short intervals. Only a history of repeated bronchopulmonary lesions justifies incrimination of gas poisoning in tuberculosis of war veterans.

Calcium Oxalate in the Cerebrospinal Fluid and in the Blood.—Guillaumin asserts that the exact amount of calcium oxalate in normal cerebrospinal fluid and in blood serum cannot be determined with the present methods of measurement. Obviously, it is less than 0.002 Gm. per liter. In pathologic conditions, the oxalate content of the blood may range between 0.002 and 0.015 Gm., never exceeding 0.04 Gm. per liter. Oxalemia was found in obesity, diabetes, gout and uremia.

Cystinuria in Tuberculosis.—Defective sulphur metabolism is one of the nutritional disturbances occurring in tuberculosis. The incompletely oxidized sulphur appears in the urine mostly in the form of cystine. The latter was found in the urine of over 40 per cent of tuberculous patients. The cystinuria apparently results from an insufficient aminoacidolytic functioning of the liver. On normal functioning, the cystine is transformed into taurin.

Antigen Property of Bacteriophages.—Wollman and Wollman experimented on antidysenteric and antityphoid bacteriophages that have been in contact only with corresponding bacilli. Serum prepared with the antityphoid bacteriophage was found to neutralize not only the lytic action of the bacteriophage on the typhoid and the Shiga bacilli, but also the action of the antidysenteric bacteriophage on the two bacilli. Moreover, while the antityphoid bacteriophage is without action on the bacillus of dysentery, serum prepared with this bacteriophage neutralizes the lytic action of the antidysenteric bacteriophage on both bacilli. The antigenic action of bacteriophages on micro-organisms of the same group, does not depend on their lytic action.

Bacteriology of Typhus in Man.—Fejgin, Kaczynski and Szwojnicka made 143 examinations of the blood, urine and stools of typhus patients. Several strains of the X group were isolated. The results confirm those of other authors.

Serologic Researches on the Bacillus of Whooping Cough.—Kristensen's study was made on cultures of bacillus present in the mucus and in the blood of patients with whooping cough. The patients lived in various districts of Copenhagen. Each culture served for complement fixation reaction in each of the specimens of blood. Thus a total of 100 experiments were made. All the reactions were identical. The author notes that the results disagree with those of Krumwiede, Mishulow and Oldenbusch, who found two different serologic types of the whooping cough bacillus.

Variations in the p_H of the Blood in the Course of Glycolysis.—In Roche and Roche's experience, reduction of the p_H of the blood paralleled that of the glucose. The greater and more rapid the glycolysis, the more did the p_H decrease. This explains the spontaneous disappearance of carbonic acid from the blood, observed by Evans in vitro. Evidently, in researches on glycolysis, variations in the p_H of the blood, capable of causing coagulation, should be avoided. For this purpose, a 0.3 per cent solution of sodium citrate or defibrination is effectual.

The Amount of Blood Platelets in Patients with Cancer.—Rud noted an increased amount of blood platelets in forty women with cancer of the uterine cervix. The number of the platelets exceeded the normal by 25 per cent; the increase corresponding to the gravity of the case. In cases with a complicating anemia, the excess of platelets reached about 50 per cent. Coagulation in vitro of the blood of all the patients was considerably accelerated. The phenomenon may be due to the excess of platelets or of fibrin in the blood.

Mental Confusion Following Vaccination. C. Perrens.—p. 104.
Axial Torsion of a Fibromatous Uterus. A Chauvenet.—p. 106.

Eye Disturbances of Dental Origin.—Fromaget points out the double mechanism by which the eye may become involved in the course of dental infection. Circumscribed infection of a tooth may irritate the ends of the trigeminal and sympathetic nerves, causing vasodilatation of the eye vessels. Thus reflex disturbances of the eye occur. Or bacilli may be carried by the blood stream from the dental focus to the eye, where they form a focus of infection. According to Rosenow, the infection is induced chiefly by *Streptococcus viridans*, which seems to have an elective affinity for the eye. Many transient visual disturbances are of the reflex type. They disappear as soon as the infectious process in the tooth subsides. In certain cases, the sinuses play an intermediary rôle between the dental infection and the ocular lesion. Search for the pathogenic micro-organism should be made in the blood, the periapical foci, and, especially, in the root-canals. The sinuses, as well as the dental and periapical foci, should be examined with the roentgen ray.

*Rôle of Vitamins and Insulin in Nutrition. C. Funk.—p. 389.
Medical Treatment of Cancer. A. Lumière.—p. 392.
Pneumothorax and Radiography. R. Hervé.—p. 398.
Note on Beriberi. M. Léger.—p. 402.

Rôle of Vitamins and of Insulin in Nutrition.—Substance A (vitamin A), Funk says, represents the pancreatic hormone. Substance B or anti-insulin exerts an action antagonistic to that of insulin. Substance C or co-insulin is indispensable for activation of substance A. Unlike insulin, substance A is without effect in healthy persons, while in diabetics it reduces the amount of the blood sugar. In normal conditions, the content of substance C in the blood is proportional to that of substance A. Introduction of substance A into the organism causes a surplus which cannot be activated, and consequently remains inert. In the blood of diabetic persons, substance A is deficient, while the amount of substance C is greatly increased. The fact that substance A reduces the blood sugar in diabetics is thus explained. Substance A does not cause hydremia or hypoglycemic shock which are sometimes observed with insulin. In rabbits substance B induced hyperglycemia accompanied by pancreatic disturbances. The animals lost in weight; they developed hydremia and grave anemia. Substances A and B are present in the pancreas and in the liver; they are found in almost all alimentary products. These facts may throw light on the etiology of diabetes.

*Cecal Spasm in Appendicitis. A. Fraikin.—p. 414.
*Pharyngeal Disturbances Associated with Biliary Diseases. G. Parturier and Vallerix.—p. 415.

Spasm of the Cecum in Chronic Appendicitis.—Fraikin points out the presence of cecal spasm in chronic appendicitis. The spasm can be seen in the roentgenogram. It is confined to the cecal fundus and the cecal border where the appendix is inserted. It is visible six or seven hours after a barium sulphate meal. Sometimes the spasm appears only on palpation of the cecum. The spasmodic reflex is followed by expulsion of the barium into the ascending colon. Clinically, the spasm is revealed by colic. It may be of diagnostic value in chronic appendicitis.

Pharyngeal Disturbances Associated with Biliary Diseases.—Parturier and Vallerix explain the origin of rhinopharyngeal lesions associated with biliary diseases. Rhinopharyngeal disturbances may precede or succeed those of the liver or biliary tract. Sometimes lesions develop simultaneously and independently in the liver and in the nasopharyngeal tract. Colloidoclastic shock may be a common factor in these diseases.

*Modern Theories of Vasomotion. R. Leriche and R. Fontaine.—p. 481.
Dietetic Value of Vegetables. W. Orlowski.—p. 482.

Critique of Modern Theories of Vasomotor Activity, Based on Surgical Facts.—In Leriche and Fontaine's experience, severing of all vasomotor rami in an extremity has never caused vasomotor paralysis or phenomena of vasoconstriction. The reaction to cold and to heat was conserved. In 300 operations in man and animals, severing of sympathetic nerves induced a transient vasodilatation in the opposite extremity as well as in the involved extremity; frequently in all four extremities. Severing of certain sensory nerves caused analogous phenomena of vasodilatation. Severing of mixed nerves, such as the sciatic, did not abolish vasomotor activity. Phenomena of hyperemia were observed in the involved parts a few months after the operation. Three months after extensive destruction of the spinal cord, vasomotor reactions in the lower extremities were still present. The facts contradict the classic theory according to which efferent nerves convey vasoconstrictor or vasodilator impulses from the spinal cord to the periphery. The theory that vasomotor centers are present in the arterial wall agrees better with reality, the authors say. Sensory fibers join the intra-arterial centers to the ganglionic and medullary centers.

Electrocardiography in Coronary Obliteration. A. Clerc.—p. 499.
Fracture of Astragalus with Disarticulation of Posterior Fragment. P. Feutelais.—p. 502.

Surgery for Relieving Pain.—Leriche discusses the anatomic and physiologic factors of pain. He concludes that it is frequently difficult to establish the exact location of pain. Hence, removal of ganglions may be without effect; furthermore, it is not yet known how detrimental the operation is. Leriche warns against posterior radicotomy. Relief of pain is not always attained. He is against cordotomy, although the operation was introduced into France by himself. Neurotomy requires certain precautions. It should be borne in mind that anastomosis of the superior cervical ganglion with vagal fibers is possible. Overlooking of the fact may result in paralysis of the palate and of the vocal cords. In interventions on the lumbar sympathetic, the lymphatics should be respected; while in periarterial sympathectomy care must be taken not to injure the arteries, to avert thrombosis. The chief cause of recurrence of pain after neurotomy is the formation of a neuroma on the nerve scar. The neuroma must be excised at a supplementary operation. A method for preventing neurogliomatous proliferation in the nerve-stumps is needed.

New Cause of Occupational Carbon Monoxide Poisoning.—Heim de Balsac, Agasse-Lafont and Feil call attention to a form of chronic carbon monoxide poisoning from what is known as "poor gas." This gas is tending to replace illuminating gas in factories, also gasoline in automobile traction. It contains from 25 to 27 per cent of carbon monoxide. The lighting and heating power of the gas is below that of coal gas; but its cost is only one twelfth as much. The manufacturing of the gas is without danger. Poisoning is due to escape through crevices in the receptacle.

*Clinical Study of Substance A of Insulin. M Landsberg —p 242.
*Note on Substance A. C. Funk —p 245
Mental and Nervous Derangement Following Cerebral Thrombosis A. Forel —p 245.

Clinical Study of Substance A Isolated from Insulin.—Substance A, isolated by Funk from insulin, was used by Landsberg in diabetic and nondiabetic persons. A dose of 0.012 Gm. of the substance, corresponding to 20 units of insulin, was injected subcutaneously in the fasting patient In diabetic patients the blood sugar was reduced by from 0.041 to 0.109 Gm., an hour and a half after the injection. Some of these patients were given insulin, the reduction of the blood sugar was scarcely larger than that from substance A. Administered by the mouth, the latter proved to be without effect In nondiabetic persons, substance A did not decrease the blood sugar appreciably. Shock did not occur in two cases of considerable hypoglycemia caused by substance A. It is probable that the substance in insulin which induces shock is not the same as that which induces hypoglycemia.

Use of Substance A of Insulin in Diabetic Patients with Cardiac Lesions.—Funk states that isolated substance A may not be of much therapeutic importance in diabetes, until it becomes possible to isolate also the activating substance C Nevertheless, in diabetic patients with cardiac lesions, who do not tolerate insulin, substance A, which is chemically pure and is atoxic, can be advantageously employed.

22: 85-132 (Feb) 1927

*Magnesium Sulphate in Treatment of Eclampsia J. L Wodon —p 85.
Chronic Nephritis and Pregnancy. R. Beckers —p 92

Magnesium Sulphate in Treatment of Eclampsia.—Wodon asserts that magnesium sulphate may advantageously replace hypnotics in treatment of eclamptic convulsions A dose of 3.5 or 4 Gm. of magnesium sulphate, in a 10 to 50 per cent solution, is used for one intramuscular injection The injection may be repeated after an hour. The total number of injections is determined by the gravity of the case. The convulsions usually subside after the first injection Magnesium sulphate does not affect the contractility of the uterine muscle, the pulse or the blood pressure. It possesses a diuretic action. The favorable action on the comatose condition is explained by reduction of the cerebral edema present in eclampsia. The treatment is without effect on eclamptic convulsions with uremia. The action of magnesium sulphate is explained by an ion mechanism An ion of magnesium sulphate is capable of replacing an ion of calcium Administration of the former results in liberation of calcium in the blood, and consequently in subsidence of convulsions caused by hypocalcemia.

*Study of Bartonella Muris T. Battistini and P Weiss —p 71
*Vaccination Therapy in Carrion's Disease O Hercelles —p 94
Significance of Freud's Work H F. Delgado —p 105.

Bartonella Muris in Lima Rats.—Battistini and Weiss examined twelve rats for *Bartonella muris* In five animals it was found in the circulating blood and in smears of splenic pulp In the blood it was detected after a ten minutes' search The presence of this micro-organism in animals without any apparent sign of anemia and its location in the cells of the reticulo-endothelial system speaks for its parasitic nature. The blood syndrome accompanying bartonellemia in rats is similar to that observed in verruga peruana There are morphologic differences between *Bartonella muris* and *Bartonella bacilliformis*. The results of transference experiments were negative in monkeys, guinea-pigs, both normal and splenectomized, and white rats.

Vaccine Therapy in Severe Carrion's Disease.—From several severe cases of Carrion's disease, Hercelles secured blood cultures, which he used to prepare a vaccine This vaccine was tried in a number of cases, and the patients recovered without developing warts An inoculation of the cultures in a monkey caused chills and rise of temperature Intratesticular injection in a rabbit was not followed by significant change.

*Strawberry Gallbladder E Ribas Ribas —p 77
Surgical Treatment of Fractures of Extremities L Bosch Aviles —p 81.

Study of the Strawberry Gallbladder.—Among 300 cases of gallstones in which he operated, Ribas found fourteen typical "strawberry" gallbladders In all the preoperative diagnosis had been cholecystitis with stones; but in only two were stones found and they were very small. Inflammatory processes, also, were present in only two cases All the patients were young women In seven cases histologic examination brought to light an accumulation of lipoid or cholesteroid in the epithelial cells It seems hard to explain the attacks of pain in such gallbladders with no gross lesions and trifling microscopic changes Perhaps the cause lies in the pressure exerted on the nerve by the accumulated cholesterol.

Meningitis Following Scarlet Fever.—In a boy, aged 7, after a mild attack of scarlet fever, an ear complication developed and finally a streptococcic meningitis The patient recovered after treatment with streptococcus scarlet fever toxin

Rupia in a Case of Late Congenital Syphilis.—Navarro and Travella's patient was a girl, aged 10, who presented various stigmas Several extensive and rather deep ulcers had developed Since antisyphilitic treatment did not prove effective, surgery was cautiously used to remove the necrosed tissues The result was most satisfactory. The enlargement of the liver and spleen has not altered. The Wassermann reaction is still strongly positive

*Disease and Death of Don Carlos J Sanchis Banus —p 493.
Iodine in Hyperthyroidism E Carrasco Cadenas —p. 512

Disease and Death of Philip II's Son.—Historians have often discussed the circumstances surrounding the death of Don Carlos, heir to the Spanish crown. Sanchis Banús studied critically the fragmentary data available. According to him, Carlos was descended on both sides from a catatonic schizophrenic great grandmother, and had for a grandfather a pathetic idealistic schizoid, and for father a "cold despot" He suffered, in his turn, from paranoid schizophrenia His death came naturally from the same cause. This agrees with the clinical picture, there is little in favor of poisoning The first to suggest the latter hypothesis was Watson, the English ambassador at Madrid at the time. "History becomes at last a branch of biology"

A Case of Hemolytic Anemia. L. de Marval and M. Benaros.—p. 869.
Brain Diseases. A. S. Marotta.—p. 875.

Acute Manifestations of Leprosy.—Among the 6,500 lepers *isolated in government leprosariums in Colombia*, Barrera and Peña have seen, as a regular phenomenon, the acute attacks on the chronic soil of leprosy which McDonald calls "leprous fever." These flare-ups may change the tubercular type into the maculo-anesthetic, or vice versa. On recovering, the patient may show remarkable improvement; however, if the attacks are very severe and close together, the resultant weakening may darken the prognosis. These acute attacks are a defense reaction. Between the inflammatory nodule and the chronic tubercle, there are anatomic differences. During the attacks, the *Bacillus leprae* exhibits signs of degeneration. From a preventive standpoint, it must be kept in mind that the patients disseminate bacilli in much greater quantities during such flare-ups. No treatment has proved very successful against this "fever." As soon as the attack subsides, the chaulmoogra oil treatment must be renewed.

Compulsory Vitaminization of Infant Food.—The lack of vitamin B in infant foods—milk, flour, juices—compels, Collazo and Goslino assert, the introduction of vitaminizing methods. They suggest the addition of autolized brewers' yeast. The methods used in concentration must be exclusively physical. The natural vitamin content is not enough. This procedure does not change any of the fundamental characters of the products. Its efficiency was proved on pigeons. As soon as the meaning of the word "vitamin" is established and methods for determining the presence of the vitamin are agreed upon, the sale of unvitaminized infant foods should be forbidden.

*Tuberculin Treatment of Leprosy. S. de Novaes e Silva.—p. 83.

Tuberculin in the Treatment of Leprosy.—Novaes tried the effect of tuberculin in three lepers, one of each type. The skin and anesthestic cases reacted well, but the latter more slowly. The therapeutic result was almost nil in the nervous case. Tuberculin does not cause violent reactions if its use is carefully controlled. It stops the nasal discharge, thus decreasing the danger of contagion.

Scarlet Fever. H. Buschmann.—p. 280.
The Dick and Schick Tests. W. Schultz.—p. 287.

Cylindruria from Acidified Milk.—Bernuth and Duken, experimenting on cats, found that administration of milk mixed with hydrochloric acid caused only a moderate injury to the kidneys. In about 60 per cent of the infants fed with the mixture, granulated casts appear in the urine. Albumin is practically absent.

Infantile Paralysis of the Vegetative Nervous System.—Selter claims priority in the description of acrodynia, which he published in 1903 under the name "trophodermatoneurosis." He now believes that it is an infectious disease localized in the centers of the vegetative nervous system and suggests the name mentioned in the title.

Avitaminosis, Blood Platelets and Erythrocytes.—Sherif and Baum observed a pronounced thrombopenia on diets lacking in (antixerophthalmic) vitamin A. Absence of the antirachitic factor causes thrombopenia in all animals and in 50 per cent of children subjected to such diets. Lack of vitamin B or C did not influence the number of blood platelets.

Subungual Tumors.—Carstensen reviews the literature on subungual tumors and reports one of Rodelius's cases. A woman, aged 27, had suffered for twelve years with pains in the tip of the right index finger. There was a small red point under the nail, which gradually became larger. For the last two years the slightest touch was enough to elicit extreme pain. On examination a bluish-red spot, the size of a lentil, was seen under the nail. When pressure was made on the free margin of the nail, the outline of blood vessels appeared over this spot. Subungual angioma was diagnosed. A roentgenogram, lateral exposure, showed an indentation in the bone of the terminal phalanx, corresponding to the bluish-red spot under the nail. The nail was removed. A round tumor, the size of a pea, was found and was enucleated without trouble. The periosteum of the bony cavity into which the tumor fitted was intact. Nine months later, the nail had regrown and was entirely normal. The histologic specimens are described in detail. The tumor cells were large, varied in shape and resembled epithelial cells. They were situated directly on the vascular endothelium. The growth resembled in structure three subungual tumors reported in the literature as angiosarcomas. These tumors the author regards as endothelioma or perithelioma. To the tumor in Rodelius's case she gives the designation endothelioma perivasculare. The diagnosis may be made from the localized pain alone, changes in the nail being absent. It is more difficult when, on the other hand, it must be made from the changes in the nail, without pain.

Pathogenesis of Cardiac Asthma. E. Wiechmann and J. Löer.—p. 372.

Blood Groups in Hypertension.—Wiechmann and Paal determined the blood groups in 500 patients with high blood pressure. They found a high percentage of groups B and AB. Hypertension occurs earlier in men than in women. Up to the age of 60 it is relatively more frequent in men, after that in women.

Permeability for Dextrose in Epinephrine Diabetes.—Wiechmann concludes from his simultaneous determinations of dextrose in the arterial and venous blood that epinephrine inhibits the intake of dextrose by the peripheral tissues.

Epinephrine diabetes in this respect resembles pancreatic diabetes.

History of Iodine Treatment.—Veil and Sturm publish a historical study of the use of iodine and of preparations that were employed long before the active principle was discovered.

"Words to Physicians and Medical Students." A. Borchard.—p. 627.

Optimal Concentration in Chemotherapy.—Kroó and Mano obtained much better results in treatment of recurrens spirochetosis of mice with diluted solutions of arsphenamine than with more concentrated solutions. The same amount of the drug administered in 1 cc. of water cured all the mice, while relapses occurred in 42.9 per cent of the animals in which 0.1 cc. of water was used. Similar results were obtained with a gold preparation, while potassium antimony tartrate acted more powerfully in concentrated solutions. They believe that the dilute solutions enhance the action in drugs which require an oxidation to become effective. The concentrated solution should be used in drugs which become less active when oxidized.

Sign of Detached Placenta.—A distressing feeling of pressure on the rectum when the placenta had entered the vagina was noted regularly by Calmann in his parturient patients.

"Eggs in the Diet in Spasmophilia." W. Wernstedt.—p. 307.

Diet in Exsiccosis.—Schiff and Bayer found that symptoms of toxicosis can be produced experimentally by administration of proteins only in acute depletion of the water reserves of the organism. They treat toxicosis by administration of Ringer's solution or whey containing 15 per cent of milk sugar. Cane sugar is probably just as good. Sometimes it is necessary to add an intravenous injection of 150 to 200 cc. of Ringer's solution containing 5 per cent of dextrose.

Blood Sugar Regulation in Rickets.—König and Lenart found a steeper alimentary glycemia curve in children with rickets than in controls. The hyperglycemia also lasted longer than in the normal children.

Chemistry of Vitamins. E. Remy.—p. 444.

Changes in Incidence and Character of Internal Diseases.—Magnus-Levy suggested the German questionnaire on the frequency of pernicious anemia. He mentions various clinical conditions which have changed in his lifetime, either in appearance or in frequency. Cirrhosis of the liver, jaundice, gout, diabetes, dilatation of the stomach, aneurysms and general paralysis have changed. Delirium tremens has become rare, as well as the typical turbulent anesthesia of drunkards. Chlorosis is vanishing, while pernicious anemia seems to be increasing in frequency.

Glycolysis and Rickets.—Brock and Welcker found in rachitic rats the same absence of glycolysis in the blood that Freudenberg and Welcker observed in rachitic children The blood phosphates were low The formation of lactic acid in the liver was reduced about one half. The striated muscles from these rats had a normal content of phosphates and of hexose-phosphoric acid

A New Sign in Premature Infants.—Finkelstein and Wilfand observed a peculiar phenomenon in prematurely born infants. When the infant lies on its side, the lower half of the body becomes bluish red, and the upper half pale The dividing line is sharply defined and localized exactly in the middle line of the body (including the head). They believe that the phenomenon can be explained only by assuming two vasomotor centers and underdevelopment of commissural paths between them The symptom disappears when the infant reaches the age of two to three months.

Reindeer Milk.—Ylppo found that this milk contains about six times more fat and salts than does human milk He found 18 7 per cent of fat, 11 1 per cent of proteins and 1 2 per cent of ash in it Consequently, children fed on it suffer from thirst and do not thrive.

Hemoglobin Resistance in Anemias.—Worpel found an increased resistance of hemoglobin to sodium hydroxide in all of his forty patients with pernicious anemia. The resistance was temporarily low in only one of them. Hemoglobin from patients with secondary anemia was normal except where there had been grave acute hemorrhages; here the resistance was increased for some time. It seems that immature hemoglobin is more resistant. He used Bischoff's method: addition of 1 cc. of fourth normal sodium hydroxide to 5 cc of a 1 per cent (by Sahli's hemometer) solution of hemoglobin and observation of the time when the oxyhemoglobin spectrum disappears. This time is about 60 5 seconds in healthy adults—a little less in women—and increases in pernicious anemia—to from 68 to 230. There is a parallelism between the gravity of the condition and the time of destruction of hemoglobin.

Metabolism After Blood Transfusions in Anemia.—Weicksel always found a negative nitrogen balance during the exacerbation of pernicious anemia.

Epinephrine and Acetone.—Hirschhorn and Pollak found an increase in acetonuria after an injection of epinephrine, in cases of spontaneous acetonuria (pregnancy, infectious diseases, asthma) or in acetonuria induced by a diet free from carbohydrates. This action may be prevented by administration of carbohydrates. The epinephrine acidosis is marked in some cases of diabetes, slight in others.

The Thyroid, the Vegetative System and the Blood.—Rothschild and Jacobsohn administered thyroid substance and observed a sympathetic effect: increase in blood cholesterol and calcium and lowering of the total phosphorus, potassium and residual nitrogen Ergotamine has the opposite (vagal) effect in patients with exophthalmic goiter, but its action in animals is chiefly sympathetic. Choline lowers the blood sugar and the cholesterol.

Chronic Diffuse Interstitial Nephritis.—Lowenthal reports a unique case of a pure interstitial nephritis without apparent injury to the glomeruli and with only a compression of the tubules. The patient was an insufficiently treated syphilitic and died of cachexia Gastric symptoms (achylia and vomiting) were the most prominent clinical feature. The changes in the kidneys were unexpected.

A Gynecologic Sign of Appendicitis.—Thickening, shortening and painfulness of the sacro-uterine ligaments, when it is present only, or mainly, on the right side, is a reliable sign of appendicitis, Sellheim states, if gonorrhea and puerperal infection can be ruled out.

Phrenicotomy in Traumatic Perforation of the Lung.—Haim performed phrenicotomy, as a preliminary operation to thoracotomy, rib resection and lung suture, in a case of stab injury to the lung. He believes that it furthered healing by putting the lung at rest and by raising the diaphragm and thereby rapidly emptying the pleural cavity of blood.

*A Danger in Kocher's Operation for Hernia. M. Lipscher.—p. 467.

Suture of the Peritoneum After Appendectomy.—Frank applies a soft intestinal clamp to a fold of cecum containing the stump. The resistance to the needle thus obtained greatly facilitates suturing.

Extramuscular Perineal Prostatectomy.—Haim finds that, contrary to general opinion, the external anal sphincter can easily be isolated from the rectum. Passing between the sphincter and the rectum and avoiding the muscular network where the fibers of the sphincter, the bulbo cavernosus and the superficial and deep transversis perinei meet, one arrives in the space between the rectum on one side and the urethra, prostate, bladder and seminal vesicles on the other. The space contains only the soft connective tissue of the rectovesical septum. With spatulas the sphincter is drawn forward and upward, the rectum forward and downward. The bladder, or at least the urethra, must be pressed outward with a metal catheter. Advantages of the method are, according to Haim, absence of shock, of the necessity for complicated dressings and of a visible scar; the operation can readily be done under local anesthesia and does not need to be broken off, if injury to the urethra or bladder should occur.

A Danger in Kocher's Operation for Hernia.—In operating on a small, right inguinal hernia in a boy, aged 10, Lipscher included a portion of intestinal wall in the clamp with the sac and sutured it to the lateral abdominal wall in the region of the internal inguinal ring. The error was discovered at a second operation four days later. The abdominal cavity contained 200 cc. of thick pus. The child recovered.

Explosions of Anesthetic Gases.—In opening a suppurative process in the lungs otherwise than with the knife, Lotheissen uses local anesthesia exclusively, because of the danger of explosion with ether or ether and oxygen and the risk of heart failure with chloroform.

Philology in Surgery.—Harth of Athens takes exception to certain philologic strictures made by Reinberg in a recent number of the same journal. The *th* in *epithelium* is correct, for the word is not derived from ἐπιτέλλω, but from ἐπί and θηλή (*on* and *nipple*) and was first used by the Dutch anatomist Ruysch for the fine epidermis covering the nipple and tactile papillae of the margin of the lip. *Arrhythmia* is correctly written with two *r*'s because of the rule of grammar which doubles ρ after a short vowel (α privative) in compounds. Catarrh is another example. Reinberg thinks that *trocar* has been derived from *trois-quart* by popular etymology, whereas, Harth maintains, *trois-quarts* is the original and technically correct term, which he explains by the three right-angled triangles which together form the point.

Crossed Colic and Crossed Functional Disturbance in Nephrolithiasis.—In the case here described, the right kidney contained a calculus filling the entire pelvis, but there were no symptoms on the part of this kidney and it continued to function, whereas there had been attacks of colic in the left kidney and indigo carmin tests had shown a temporary complete cessation of function in it.

Vaccination Against Puerperal Infection E J Jankelewitsch—p 436.

Results of Radium Treatment of Carcinoma of the Uterus.—Ikeda's statistics, which are from Japan, cover a period of twelve years. Of 432 patients treated with radium for carcinoma of the cervix, 198 are now alive. One hundred and sixteen of these have lived longer than five years, seventeen longer than ten years after the treatment. In nine of those living the tumor has recurred. He finds that most local recurrences and metatases occur during the second year. There were two cases of acute septic peritonitis caused by the irradiation. Two pregnancies (two and three months, respectively) were terminated by spontaneous abortion during the irradiation. Five women who were in the latter half of pregnancy at the time of the irradiation carried their children to term and were delivered normally. These children have all thriven and show no abnormalities. Three of these *five women again became pregnant, but they died during* childbirth. The children lived. The cause of death was given as hemorrhage; it is probable that scar formation in the birth passage caused difficult parturition.

Influence of Prophylactic Vaccination on the Course of the Puerperium.—Three hundred women were vaccinated against puerperal infection, 100 were given an intramuscular injection of 100 millions of streptococci and 400 millions of staphylococci twenty days before term and a second injection ten days before term. One hundred received a single intramuscular injection of 25 millions of streptococci and 200 millions of staphylococci on admission to the clinic, i. e., during labor. In this group the results were not fully satisfactory, and the next hundred women were given further injections, one of 50 millions of streptococci and 200 millions of staphylococci forty-eight hours after the first (whether or not the birth had taken place) and one of 100 millions of streptococci and 400 millions of staphylococci after a further forty-eight hours. The results in the first and third groups were approximately the same: the puerperium was normal in 94.6 per cent, febrile in 1.8 per cent, subfebrile in 0 per cent, in 3.6 per cent the temperature rose once to 38.5 C. Three hundred unvaccinated women were used as controls. For these the corresponding figures were 70.3, 21.9, 5, and 2.8. The high percentage of infections is explained by the bad economic condition. A general reaction, usually severe, was noted in 59.5 per cent of the women vaccinated in the course of the pregnancy, a local reaction in all. The preparation of the vaccine is described. It should not be more than two months old.

The Cerebrospinal Fluid in General Paralysis and Other Mental Diseases A L Barsuk—p 48

Mechanism of Inorganic Cardiac Murmurs.—Treguboff found inorganic systolic murmurs most frequently in neurasthenic persons. The murmurs were associated with other signs of cardiac neurosis, as palpitations, pain in the cardiac region and dyspnea. Savitskiy's experiments on isolated animal hearts indicated that hyperexcitability of vagal fibers, innervating the papillary muscles, is responsible for the inorganic murmurs. The theory was verified on epinephrine and atropine tests, in patients with cardiac neurosis. Under the influence of epinephrine, the intensity of the systolic murmurs increased; under the influence of atropine, the murmurs disappeared. There was evidence that the results were independent of the blood pressure. Hypertension of the chordae tendineae, due to spastic contraction of the papillary muscles, causes insufficiency of the valves. Consequently murmur occurs. Atropine appeared to be without influence on organic systolic murmurs. In dubious cases, the atropine test may aid in the differentiation of organic from inorganic murmurs.

*Agglutination Reaction for Determination of Blood Groups. G. Alieff.—p. 55.
Compression of Spinal Cord in Tuberculous Spondylitis. M. M. Ammosoff.—p. 88.

Secretory Functioning in Isolated Segment of Ileum Used for Baldwin's Operation.—Clinical observations on the secretory functioning of the intestine were made by Vakar on a segment of the ileum used for the construction of an artificial vagina. Mechanical irritation, as from a drainage tube, or chemical irritation from irrigations stimulated the secretion of intestinal juice. The secretion was reduced by administration of belladonna; it increased greatly after ingestion of food. There was a connection between the amount of the secretion and the kind of food taken. The intestinal juice can be easily preserved at room temperature, even in an open tube. It appears that isolated segments of intestine can serve for researches on the physiology and pathology of intestinal secretion in man.

Agglutination Reaction in Determination of Blood Groups.—Alieff's method of determining the group to which a certain blood spot belongs is as follows: About 1 cc. of plasma or of serum of the first group is mixed with from 0.1 to 1 Gm. of the dry blood to be examined. The mixture is kept in the thermostat at 37 C. for from two to five minutes. If the mixture agglutinates washed or fresh erythrocytes belonging to the second group, but does not agglutinate those belonging to the third group, the blood tested is of the third group. If the mixture agglutinates erythrocytes of the third group, but does not agglutinate those of the second group, the blood in question is of the second group; if the mixture does not agglutinate erythrocytes of either the second or third groups, it means that the blood belongs to the fourth group; agglutination of the erythrocytes of both the second and third groups points to the first group. Evidently agglutinogens are not destroyed in desiccated blood. The ability to absorb agglutinins is preserved in them at least for eight weeks. The author lays stress on the value of this method in forensic medicine.

Etiology of Erythema Nodosum. J. C. Berntrop, Jr.—p. 1325.

Tar Carcinomas in Rabbits.—Two rabbits were each given thirteen treatments with tar on the skin of the back. In one a skin carcinoma developed, which metastasized in the lymph glands of the same side. In the other there developed an ulcerating papilloma, which was excised and on microscopic examination presented evidences of early carcinomatous degeneration. Three months later nothing abnormal was to be found in the animal. A rabbit was then treated with tar in and around the mouth, with the object of studying the effects of tar on the intestinal canal. Forty treatments were given, two a week from December to May. In June a number of papillomas and an ulcer developed in the skin of the sacral region. Biopsy showed the ulcer to be a beginning carcinoma. Seven weeks later there were metastases in the groin. In the same animal pieces of the tumor were inserted under the skin in the neck, in the inner side of one ear and in the outer side of the other ear. Pieces of one of these grafts were inserted under the skin on the inner surface of both ears in eight rabbits that had never been tarred. In one of these animals a tumor, histologically carcinoma, developed in each ear on the site of the graft—further attempts at grafting were unsuccessful. The tarred rabbit died about five months after the appearance of the first lesions. The gross and microscopic appearance of the lesions in this animal is described in detail.

Hemorrhagic Swelling of the Fetus as Birth Obstruction.—A primipara, seven months pregnant, showed signs of hydramnion. Labor set in and proceeded very slowly. Forcible extraction of the head was successful after a number of attempts, but further efforts were fruitless. The obstruction proved to be a swelling of the skin over the left half of the back, thorax and abdomen and on the left arm. The skin over these regions was so softened that the examining finger was able to pierce it, whereupon a large quantity of bloody fluid escaped, and it became possible to extract the fetus.

Nomogram for Hematologic Use. E. J. Warburg.—p. 187. In English.
Extrasystolic Bigeminy. E. Zander.—p. 189.

Hemoglobinuria from Cold.—Höglund reports two cases of paroxysmal hemoglobinuria. Absorption of the cold hemolysins increased the subsequent titer of the serum in the Wassermann reaction. The cold hemolysins may be present even if the Wassermann reaction becomes negative.

Sprue in Denmark.—Holst observed a case in a woman who had never left Denmark. The patient's muscles were atrophic and she also had spastic paraplegia and spontaneous fractures of the ribs. The latter, together with the tetany, are attributed to loss of calcium through the feces in the form of calcium soaps. The blood sugar did not increase after administration of 50 Gm. of dextrose. There was some azotorrhea, but this does not exclude the diagnosis of sprue. The stomach secretion was acid, but megalocytes were increased in the blood.

Diabetes Mellitus and Hypoglycemia.—Rosendahl's patient developed hypoglycemia after being treated for a few days with Petrén's diet and small doses of insulin. The insulin was discontinued and injections of dextrose used. In spite of this, the attacks of hypoglycemia returned and the patient died. An alkalosis together with acetonuria was observed during the attacks. There was also an excess of chlorides and nitrogen (especially ammonia) in the urine. The author attributes the hypoglycemia to insufficiency of the liver.

Erythrocytes in Pernicious Anemia.—In wet preparations Jørgensen and Warburg found the mean diameter of erythrocytes from healthy subjects to be 7.7 microns. A diameter of 8.6 microns or more in more than 15 per cent of the erythrocytes is extremely suggestive of pernicious anemia. Microcytes are as a rule thicker, macrocytes thinner than normal erythrocytes. Jaundice may cause macrocytosis, although the latter is not proportional to the bilirubinemia. Microcytosis is frequent in hyperthyroidism. The percentage of macrocytes is increased not only in pernicious anemia (and sprue) but also in Jaksch's anemia, tumors of the bone marrow, some cases of leukemia, severe malaria and after various hemolytic poisons (nitrobenzene, benzine and pyrogallol), in poisoning by lead or radio-active substances, in hypothyroidism and in a few patients with cancer of the stomach.

THE TREND OF SURGERY *

J. TATE MASON, M.D.

SEATTLE

Progress is the watchword of science. It would be stimulating to sketch the splendid developments in surgery during the past generations, the observations that transformed the science of surgery from a series of barbarous and hazardous experiments on suffering humanity to a comparatively safe and reliable method of overcoming disease and restoring health; but I shall confine what I have to say to a few observations based largely on my own experience. One cannot look back without a sense of pride and satisfaction to what has been accomplished during the past quarter of a century.

Speculation as to the future and occasionally the outlining of changes for the betterment of conditions as a whole are especially needed in the field of surgery where, many times, an operation is the ultimate effort on the part of the patient and surgeon to remedy a condition that has baffled other branches of medicine. Since it is impossible now for any individual to master all the branches of medicine, it has been necessary to receive guidance and advice from the pathologist, the biochemist, the neurologist, the endocrinologist, the internist and others. From the reports and advice of these groups of men, the surgeon must formulate his plans and finally carry them into completion in each case.

COMMON SURGICAL SENSE

From the well equipped roentgen-ray, clinical and pathologic laboratories which are at the disposal of the practitioner come many reports whose interpretation may indicate a probable diagnosis. This wealth of information may occasionally be confusing. The surgeon of the future should not lose, with all these advantages, the use of his own special senses. The seeing of an hysterical patient, the feeling of the hot, trembling hand of an exophthalmic goiter patient, the noting of the sound of the peristaltic wave of the small intestine, or the odor of the typhoid and the diphtheritic patient, the recognition by taste of certain narcotics are diagnostically characteristic. It is to be hoped that the surgeon of the future will not lose the power to gain information by the use of his own senses. Let him keep his own special primitive detective forces at work no matter how many other gatherers of scientific data he may have at work for him.

TRAINING THE YOUNGER MAN

Up to ten years ago a majority of the younger men received the major part of their surgical experience at the expense of the patient. Positions as assistants to men of recognized ability were scarce as compared with the number of applicants. This condition of affairs has changed, and in many places a young man receives enough to live on during his training. If progress in surgery and surgical diagnosis is to continue, it must become the duty of every active surgeon to train regularly a few men and to see that, during this period of training, the younger man is cared for financially. When a poorly trained man appears in our midst it is probable that he is less to blame than the older and better trained surgeons who should have seen that he was properly trained before allowing him to set out for himself. It is sad to read at times that one of the great leaders of surgery has passed on, and shocking to realize that this man, who meant so much to his immediate community and the state at large, has left no one to carry on his work.

THE GENERAL PRACTITIONER AND SOME EMERGENCY CASES

There are emergency conditions, such as appendicitis, strangulated hernia and ruptured peptic ulcer, in which the element of time is of utmost importance. In some sections of the country where distances are great, a number of unfortunate persons pay the extreme penalty each year because of their remoteness from competent surgical help. Consequently, the education and training of the general practitioner whose duty it is to look after these isolated communities should be such as to prepare him to handle such emergency cases alone if necessary. Intensive study should be given by him to the conditions which he is most likely to be called on to combat. Occasionally a physician witnesses a long and complicated operation which is a complete waste of his time and patience, as he never expects to perform such an operation. He would be much more benefited by a short and intensive course in the most common ways to handle emergency cases with what facilities he has at his command. A kitchen table or a small obstetric hospital may be his operating theater. Such qualifications of the general practitioner, plus an understanding of his limitations, would save many from death each year and would eliminate much pain and suffering and save many weeks of hospitalization for patients.

Many practitioners are so situated that they have to brave severe weather conditions and bad roads in attending to the details of a general practice. In spite of the constant grind they have equipped themselves to perform emergency operations when absolutely necessary. The number of men so qualified is constantly increasing, and they certainly deserve all the credit that has ever been given to any medical man for services rendered.

---

* Chairman's address, read before the Section on Surgery, General and Abdominal, at the Seventy-Eighth Annual Session of the American Medical Association, Washington, D. C., May 19, 1927.

SURGICAL FADS

Fads in surgery must be shunned like the streptococcus. Every new idea is worth consideration as important, but it should be taken up with care and caution. Most can await adoption until they have been tested by men of recognized ability. Surgeons should not rush to adopt everything new because of its newness but should await such conservative tests as are applied in internal medicine when a new drug is offered for investigation. Some authoritative surgical body should be requested each year to discuss the merits and demerits of new and old surgical technics which are offered the profession. By this, I do not mean to suggest that a surgical council should be established, as that does not seem necessary at present. But such information coming from a body of men well recognized as surgical leaders would help to standardize the work and to clarify the ideas of men unable to take the time needed to investigate and cull the wheat of fact from the chaff of fiction which appears in the medical literature.

RECOGNIZING LIMITATIONS

That there exist varying degrees of qualifications and limitations in surgical practice will probably be one of the hardest facts that we shall have to recognize in the future. No surgeon does all operations equally well, and while he may do some operations with a brilliance that will far outshine the work of the average man, he may do others with mediocre ability. It is hard to recognize our own limitations or to judge the limitations of others. The more uncompromisingly we criticize ourselves, the nearer we can approach the desired goal of 100 per cent efficiency. The general practitioner in the future should recognize that some men in certain surgical procedures are eminently qualified, while in other procedures they simply are not competent.

SURGICAL JUDGMENT

Surgical judgment is difficult to achieve, but as time goes on this will be improved. Three factors enter in: (1) the better knowledge of the surgeon of today of the chemistry, physiology and pathology of the tissues that are being operated on; (2) a well recognized standard of procedure for a certain class of work, and (3) the qualification and experience of the operator himself. That the surgeon of the future may measure up in self reliance, responsibility and judgment with the surgeon of the past, he must be better trained and thoroughly imbued with the investigative spirit. Patients present a problem to be dealt with from a scientific and a common sense standpoint. When controversies arise in regard to surgical problems, as those now with regard to the surgery of the stomach and duodenum, or peptic ulcer, the surgeon of the future will reserve his opinion until enough time has elapsed and enough cases have been studied to justify him in adopting one method. But until a preponderance of evidence of one side or the other has been definitely placed, the surgeon of the future must follow the method which seems simplest to him and with which he is most familiar. If he will recognize his limitations and do only that which he is best qualified to do, his postoperative results will be better and his percentage of cures far greater than in the past.

THE FAMILY PHYSICIAN

The gradual disappearance of the old family physician who was friend, counselor and adviser of the community in which he resided is certainly to be regretted. He was better educated outside of medicine than the physician of today. His knowledge of the psychology of medicine was often superior to our own. It is true that with the advent of large clinics practically everything of a scientific nature can be done for the patient. The specialization of different branches of medicine and the great advance in different fields of surgery has brought all branches of medicine to a degree of efficiency higher than could have been conceived in the past. Still, it must be remembered that the old doctor's high hat, long coat and friendly smile often created perfect trust and confidence, and his assurance that everything would be all right caused many a disturbed ductless gland to function properly, in a way that no skilful knife or pharmaceutical remedy *can ever equal. The passing of the old family physician* with the great qualifications admired and respected is the natural result of the demand of the layman for better medicine. The layman's increasing knowledge and understanding of many of the problems of surgery has made the passing necessary. The mass of scientific data has increased so rapidly that student and physician alike soon realized the impossibility of digesting it all, and focused attention on restricted fields of knowledge, neglecting education along nonscientific lines and even on the important subject of psychology. Some persons are instinctively good psychologists. It is a gift, but it can be cultivated. The wonderful man of the past known as the family physician passed on this, his greatest heritage, to us, and it is to be hoped that the physician of tomorrow, no matter how scientific he may be or how accurate his knowledge of the body, will not neglect to acquire the ability to give the patient and those around him a cheerful outlook and confidence and assurance of ultimate recovery.

STATE AND HOSPITAL RESEARCH LABORATORIES

Surgery today is not restricted to the larger centers as it was in the past, but excellent work is done even in the smallest communities. If these men in the smaller places are to continue to forge ahead, they must from time to time have opportunity to discuss the problems of surgery in research laboratories. In the larger centers this is now done. There is an old Chinese proverb which is true today, "To converse with a learned man for one night is better than studying books for ten years." I know one busy man who gives a half day each week to the discussion of his surgical problems with the workers in a research laboratory. This opportunity, although probably not so often as a half day a week, could be obtained easily by all of us if each state would organize a state surgical association allowing all members of the state association interested in surgical problems to contribute toward one centrally located research laboratory. Such a plan would increase the number of men in research work, stimulate the younger men to do better work, and many problems, at present unsolved, could be worked out for the benefit of medicine and mankind.

It has been stated that there are in the United States at the present time about 1,500 men devoting themselves to preclinical research work. With the additional number of workers made possible through such organizations, the establishment of research laboratories in connection with the better hospitals would soon follow. When the layman appreciates the fact that the surgeon of today, besides his manual skill and knowledge of anatomy, must have a grasp of the subjects of pathology, physiology and biochemistry undreamed of a few years ago, and when he realizes that every patient presents a problem more difficult of solution than those in any other field of science, state laws will be changed to foster research work so that not only men but animal husbandry as well will be benefited by the knowledge gained.

THE SURGEON OF TODAY

At present there are three types of trained men who are doing most of the surgery in this country. The first, and the one probably most respected by the medical profession, is the one who is associated in some teaching capacity with one of the medical schools. Some of these men are whole-time men and others have a large surgical practice outside their teaching positions. They have attained these positions usually because of scholastic ability, ambition and inclination on their part to teach. The second type of surgeon is one who has had excellent surgical training in some of the medical centers with one or two of the recognized leaders of surgery of this country. The third type of surgeon is the man who has not had any particular training but who, because of a good personality and energetic disposition, builds up a large individual practice. In this practice he begins to do the simpler surgical operations and gradually takes in a larger and larger field as the years go on until eventually his practice is all surgical. Most of the surgeons of this type do not live in the larger centers, but the class of work they are doing is, on an average, as good as any. They are men who recognize their shortcomings. They travel annually from clinic to clinic picking up here and there bits of information, gradually growing in experience, becoming more proficient year by year, until at the age of 50, from the standpoint of experience, judgment and surgical technic, they are giving to their clientele the best obtainable service. These men have reached their position in life, first because they are particularly adapted to the profession which they have chosen and, secondly, because of an ambition to carry on under what they believe to be adverse conditions. In the future they will probably not give to surgery any great discoveries, but they can, and I know that they will, stabilize the best procedures in surgery and continue to do a great volume of work.

These three types of individuals, trained under different circumstances, should in the future appreciate one another and try to accept some of the good qualities that the others have. The most deplorable state of affairs in the surgical ranks is that engendered by the man too well satisfied with himself and the conditions around him. It is a fact in surgery as well as in any other field that one must go forward. To stand still is to go backward. That such a condition is not probable, we are happily aware. The progress which has been more or less continuous for many years and which was never greater than in our time and in our country is our best guarantee that the efforts we make are to be crowned with success. There are doubtless many ills of the flesh which are beyond our skill and may always so remain, but enough has been done to show that humanity has no kindlier and more beneficent aid than that afforded by modern surgery.

1220 Federal Avenue.

RADIOLOGY *

ALBERT SOILAND, M.D.
LOS ANGELES

The word, or caption, "radiology" has been in general use for a great many years as denoting the medical application of roentgen rays, radium and allied agents. Even before radio broadcasting terms came into being and added confusion to the issue, the word "radiology" was employed in European countries as noted. It appears, therefore, that the medical profession has a prior right to the term, and in the absence of a better word to define our specialty an attempt should be made to define radiology properly and also to place a reasonable limitation on its scope.

Next in order would be the adjusting of the rather cumbersome terminology now in vogue by simplifying the words in daily use and eliminating all those which are unnecessary or unwieldy. To this end the several national radiologic societies in America have been asked to cooperate and it is to be hoped that they will respond.

It seems desirable to maintain radiology as a separate entity, and this has been made apparent, first, by the American Medical Association's authorizing a section on this subject, and, secondly, by the creation of the Council on Physical Therapy. This council has already accomplished a great deal toward separating the wheat from the chaff among the heterogeneous maze of physical and technical specialties which exist on a border line of professional respectability. It is apparent, therefore, that physical therapy in all its ramifications must be given time to clarify its own atmosphere before it can eventually emerge free from extrinsic contamination and be properly made a part of recognized scientific medicine and surgery.

The contributions of radiology to medicine and surgery are legion and need scarcely be dwelt on here. The outstanding service of the roentgen ray in diagnosis, however, may be briefly touched on. This has become a fine art, mechanically perfect and scientifically accurate.. The illumination of the entire human osseous structure is easily accomplished. The use of opaque meals and mediums, the introduction of dyes and air, permitting visualization of the hollow viscera and interorganic spaces, have revolutionized our conception of normal and pathologic anatomy; and while it appears that we cannot at present expect to reach any higher diagnostic levels, no one has had the temerity to state that the end has been reached or to prophesy what the future may hold in store.

From a therapeutic standpoint, the roentgen ray occupies a unique position. Here the radiologists are confronted with complex problems and enormous responsibilities. There is as yet no reliable standardized measurement of output, no accurate method of dosage and no immediate prospect of a purely mechanical easy procedure. Many theories as to voltage, milliamperage, distance, penetration, filters, and field selection are promulgated and generally accepted, but the ideal amalgamation of all these factors still lies in the future.

It must be obvious that it is of utmost importance for a therapeutic radiologist to be trained in the fundamental medical sciences in order to use intelligently the forces at his command. Just because the short wave roentgen ray did not immediately destroy all deep lying cancer cells, a reverse action for roentgen-ray nihilism should not be set up. We know that in suitable dosage these cells can be destroyed, and perhaps, when eventually all the factors of radiation have been brought down to simple mechanical and mathematical control, the present unstable conditions will be successfully overcome. There is ample reason to feel pleased over the good already accomplished in a large list of pathologic conditions, and it is perhaps not untimely to state that the world has not yet produced a single remedy which has exerted a greater influence on human diseases than the energy of radiation.

---

* Chairman's address, read before the Section on Radiology at the Seventy-Eighth Annual Session of the American Medical Association Washington, D. C., May 18, 1927.

With radium, the problem is more simple. Here is a constant, potential, unwavering source of radiation energy simple in form, easily adjusted to existing conditions and readily applied. One great source of disappointment has been with the radiologist himself attempting to accomplish the impossible with this agent, often bringing discredit on himself and unearned criticism on the element radium.

Not a few medical men have attempted radium therapy with a wholly insufficient supply of radium and with even lesser knowledge of the subject. Full publicity should be given such practice in order that it be discouraged and done away with. It would seem reasonable to assume that, with new discoveries of radium-bearing ore, the price should be reduced to a point at which ample quantities of pure radium salt could be available to those qualified to handle it. This would enable the use of massive doses to remote fields and perhaps cause a realization of the dreams of older radiologists, who have long looked forward to homogeneous short-wave radiation. Perhaps an appeal to those men who have apparently cornered the radium ore supply may hasten the attainment of this much desired ideal for humanity's sake.

The new Coolidge tube with its unlimited supply of beta radiation has a significant bearing on the future of radiotherapy. In the few months elapsed since Dr. Coolidge made this announcement, not sufficient time has passed to permit anything but the briefest survey of the situation. Even Dr. Coolidge himself, it is safe to assume, has not yet been able to placard all the phenomena that follow the application of his beta ray discharges under a voltage of 350,000 or more.

It is not difficult to visualize a very important place in therapy for this new arm of radiant energy, but from present indications it must be approached with extreme caution, for it appears to be truly a potential death ray in a limited sphere. On the other hand, it may prove to be a boon to humanity when thoroughly mastered.

Radiation therapy is so inseparably bound up with the cancer problem that a word may be permitted alining this subject with Blair Bell's studies on colloidal lead. In America close students of Dr. Bell's work have by no means approached his results and this also bears out my own experience.

This subject is of such singular importance, however, that it does not seem just to condemn or even discourage the method until further experience has been reported and others have been provided with the same colloidal solution that has proved so satisfactory in the hands of Blair Bell, the creator of this method, and his colleagues.

PULMONARY EMBOLISM FOLLOWING OXYGEN INJECTION OF A KNEE

SAMUEL KLEINBERG, M.D.
NEW YORK

It is almost axiomatic that we learn as much from our mistakes as from our successes. My purpose in this report is to call attention to a case in which an error in the technic of oxygen inflation of a knee joint was followed by pulmonary embolism and cardiovascular failure, and nearly resulted in a catastrophe. I have injected so many joints with oxygen without the slightest untoward result that I had come to the conclusion that the procedure is entirely harmless. During my early experience with pneumarthrosis, I often used too strong a current and injected more of the gas than was necessary, and though I did not deflate the joints I did not see any ill effects. The joint was widely distended and the superfluous gas infiltrated the subcutaneous and intermuscular planes and the muscles themselves. The gas was gradually absorbed, disappearing in from eighteen to seventy-two hours. Thus, because of its apparent harmlessness and because of its proved value I have urged a wider adoption and application of this important test.

Recently I had an experience in a case of pneumarthrosis which sharply brings to the fore the imperative need for observing rigidly every detail of the technic. The injection was performed by a house officer. Unfortunately I was not scrubbed up, so that, while the intern knew the details of the technic and had helped me in another case, I was unable to make certain that every step of the procedure was carried out accurately.

REPORT OF CASE

J. P., a youth, aged 19 years, was admitted to the hospital for an operation on the left knee. Several months previously he fell and fractured the left patella. In our outpatient department an examination disclosed a loose fragment of bone in the knee joint. When he was admitted to the indoor service, it was decided to inject the knee with oxygen to determine the exact location of the loose fragment before opening the joint.

The patient was accordingly taken to the roentgen-ray department and preparations were made for the injection of oxygen. The apparatus consisted of a nearly empty oxygen tank, so that the gas pressure would be low, and a sterile rubber tube and needle about 4 inches long. The knee was painted with iodine and then the needle was inserted at a point opposite the middle of and external to the patellar tendon. It was pushed upward, inward and backward so that its point would be behind the patella and within the joint. When the needle was inserted about 2½ inches, it appeared as if the point of the needle ought to be within the joint cavity, and the house officer said he felt the point of the needle moving freely within the joint space. A weak stream of oxygen was turned on. Immediately the patient complained of a peculiar feeling about his heart. As the boy had a nervous temperament, we did not attach sufficient importance to his complaint, and since the joint was not distended the injection was continued. Within several seconds the patient stated that he was dying and became white. The injection, which had not lasted over one-half minute, was stopped.

A hasty examination showed that the patient was pulseless, he was very pale, and the pupils were widely dilated. Stimulants were administered. Within several minutes he was given epinephrine hydrochloride subcutaneously. The heart beat could not be felt or heard and very soon respiration ceased. By this time his face was livid. Artificial respiration was begun and additional stimulants were injected. He received a second dose of epinephrine hydrochloride and caffeine sodiobenzoate subcutaneously, but to no avail. The patient was apparently dead. The artificial respiration was continued, and it was suggested as a last, though not very hopeful, procedure that epinephrine be injected directly into the heart. Hence about 10 minims (0.6 cc.) of 1:1,000 epinephrine hydrochloride was injected directly into the heart through the fourth intercostal space. This injection was made about fifteen or probably twenty minutes after the heart had stopped beating, and at least ten minutes after the patient had stopped breathing and was apparently dead. In about a minute a faint pulse was discovered in the radials. The heart beat gradually improved and color began to return to the face. In about five or ten minutes the patient began to breathe and very soon thereafter the heart action and respiration were of fair quality.

For about a half hour the patient's mouth was filled with an abundant frothy, blood-stained saliva. As the heart action improved, he became restless and moaned. He then began to shout and toss about vigorously. He was entirely unconscious and was so uncontrollable that it took several assistants to restrain him on the examining table. The cerebral and motor excitation became intense, probably as a result of overstimulation. At the end of about two hours after the accident, when it was deemed safe to move him, he was taken to a private room, was placed in a warm pack, and was given sodium bromide by rectum.

During the course of the night he calmed down and on the next day he was in fair physical condition, though entirely disoriented. The improvement continued, and in a few days he became thoroughly conscious and entirely oriented. Finally his mentality returned to normal except that, happily, he had no recollection of the accident. There was at no time any evidence of muscular twitching, paresis or paralysis. The reflexes, when examined on the day after the injection, were normal. On the tenth day he was discharged from the hospital able to walk and looking and feeling well. He was seen recently, ten weeks after the accident, and appeared in excellent condition.

A roentgenogram of the knee taken within an hour of the injection showed that there was no gas in the joint or in any of the periarticular tissues. Roentgenograms of the chest did not reveal any abnormality of the lungs or heart.

COMMENT

This occurrence draws our attention to several errors. The first was in the technic, for after the needle was in the knee, the tube was not disconnected to see whether there was any flow of blood. A return flow of blood would, of course, have indicated that the needle was in a blood vessel and not free in the joint. I remember distinctly asking the house officer whether he felt the point of the needle move about freely within a cavity, and he assured me he did. It was an error on my part not to have been scrubbed up so that I could have been certain about this very important detail. The next error was in continuing the injection of oxygen after the patient complained of discomfort about the heart. Our reason for disregarding the complaint was that the boy was of the hypersensitive type, and since the joint had not been distended, it was believed that the assistant handling the oxygen tank had not yet released any of the gas, and, therefore, the patient had no reason to complain but was simply nervous.

The happenings may be explained as follows: A continuous stream of oxygen was forced into the circulation, and by its volume and suddenness of entry the oxygen distended and occluded the lungs. From the presence of frothy saliva for a long time during the recovery, I believe that the oxygen was intercepted in the lungs and that none of it reached the central nervous system. This is I think substantiated by the fact that there was no muscle twitching, convulsions, motor paralysis or other evidence of immediate invasion of the cerebral motor mechanism. The stream of oxygen forced into the circulation distended the lungs so much that the cardiac action was embarrassed and ceased, and the function of the lungs was interrupted. The injection of the epinephrine into the heart produced such violent contractions of the cardiac muscle that the stream of blood forced into the lungs caused a rupture of the lung tissue allowing the oxygen to escape, and thus released the injurious intrathoracic pressure.

From my own experience and that of others who have injected oxygen into joints, the cerebral ventricles and the spinal canal, we know that oxygen is not harmful to soft tissues, even in very large quantities. We know also that during blood transfusions no harm results from the accidental entry of small quantities of air into the circulation. The injury in this case was, therefore, mechanical in nature.

I have not read any report of a similar case and am recording this experience, not to discourage pneumarthrosis, which in selected cases is very valuable, but to focus attention on the necessity for observing every detail of the technic. One must be sure that the point of the needle is free within the joint. At first a small amount of gas should be injected, and this should cause a distention of some part of the joint, indicating that the gas is entering the joint and nowhere else. If the joint is not distended the injection should be stopped, the needle manipulated, inserted farther, retracted, or pushed in another direction until one is certain of its position. I have found that it is best to insert the needle so that the point is behind the patella; in this situation one is not likely to enter a blood vessel. We expect discomfort in the joint that is being injected because the capsule is distended. Complaint of discomfort elsewhere should be followed immediately by cessation of the injection and investigation.

SUMMARY

In a case of pneumarthrosis, pulmonary embolism and cardiovascular failure immediately followed the accidental injection of oxygen into the circulation. The heart stopped beating first, followed in about five minutes by the cessation of respiration. Artificial respiration was instituted, but for about ten minutes the patient was apparently dead. An injection of epinephrine hydrochloride into the heart revived the patient and prevented what appeared a certain catastrophe. The accident was the result of faulty technic, which is acknowledged in detail, so that it may never happen again. The author in making this report hopes that it will not deter others from using pneumarthrosis, which is an invaluable diagnostic test in doubtful and properly selected cases.

1 West Eighty-Fifth Street.

Toxic Element in Burns.—It is the existence within the body of tissues in a state of chemical dissolution that is evidently the exciting feature of the disturbance—not an organismal decomposition, but a chemical change, and one, moreover, which results in the production of potent toxic elements. . . . It has been suggested that they are closely allied with, if not exactly similar to, histamine or pyridine. Certainly there are many points of similarity between the picture of "histamine shock" and that of the toxic stage of burns. The dangerous character of the toxemia depends on its liability to pick out and deteriorate specialized tissues—the liver cells, the delicate cells of the kidney tubules, and the chromaffin tissue of the suprarenals. The striated heart muscle is poisoned and degenerated, and the lymphoid tissue shows points of focal necrosis. It is not difficult to explain the symptoms and signs which distinguish the early stages of the toxic phase—the rise of temperature, the restlessness, the rapid pulse—each has its pathologic counterpart, but underlying all this, there is some more subtle influence which specifically and definitely deranges metabolic processes.—Fraser, John: *Brit. M. J.*, June 18, 1927.

THE OCULAR FUNDUS IN THE ACUTE TOXEMIAS

AN ANALYSIS OF EIGHT HUNDRED AND FIFTY CASES *

ALBERT L. BROWN, M.D.
CINCINNATI

The manifestations in many general conditions, as revealed by the ocular fundus, have been analyzed as to type and incidence on a comparative basis. These tabulations are of the greatest benefit to the ophthalmologist in aiding the internist and surgeon in diagnosis and prognosis.

The toxemias are treated separately in the literature, although there are certain signs that are common to all. They are all acute infectious processes with many fundamental pathologic similarities. Since the toxemias quickly showed generalized symptoms, it was thought that the eyegrounds might be seen to participate more or less uniformly if a sufficient number of cases of all types were studied. To this end, the eyes of every patient admitted to the medical wards of the Cincinnati General Hospital were examined as a matter of routine. Only the fundus observations in the acute toxemias are considered here. The word "lesion" henceforth will refer only to those of the fundi.

The literature abounds in reports of ocular derangements associated with these diseases. It would be pointless, so far as the purpose of this study is concerned, to compile an extensive survey of them. In this analysis I present certain conditions in the fundi which are not characteristic of any one disease but are common to all, and which occur with sufficient frequency to make them noteworthy.

The type of ocular lesions found in patients in a medical service differ markedly from those found in an eye clinic. Those found in medical patients are apt to be less widespread, and of a more transient character with less destruction to tissue and vision. The conditions encountered in an eye clinic cause ocular symptoms chiefly, such as disturbance of vision or pain, and are usually more widespread, destructive and permanent. Only 3 per cent of the patients examined had any ocular complaint other than the simple statement that they wore glasses.

Fifty-two per cent (440) of the patients presented abnormal fundus conditions which were considered to be dependent on some constitutional condition. Eighty-five per cent (374), or 44 per cent of the 850, were considered to be dependent on the acute toxic processes for which the patients were then being treated. The lesions reported exclude all thought to be due to retinal arteriosclerosis, or renal or diabetic diseases.

After the first seventy-five cases were observed, it was evident that there were certain deviations from the normal occurring with some regularity. They appeared to be dependent on the type and especially the severity of the infection. They changed with the course of the disease, became less marked when the temperature fell and the infection seemed to be subsiding, and advanced when the disease seemed to be progressing. A search of the literature and a limited correspondence failed to reveal reports of similar observations. Sir William Willcox,[1] in a discussion, said that he had recently been interested in the ocular fundus in toxemia. He simply mentioned hemorrhages as one manifestation.

GENERAL MANIFESTATIONS

These manifestations could be grouped into three classes:

1. Toxemias of mild intensity and short course: (*a*) disks normal or slightly hyperemic, with vessels (especially the veins) slightly dilated. Associated chiefly with influenza, acute rhinitis and acute sinusitis of moderate intensity. (*b*) Average temperature 100 F. (*c*) Average duration from four to five days.

2. Toxemias of moderate severity and longer course: (*a*) Disks rather hyperemic, margins occasionally blurred; vessels definitely dilated, and often slightly tortuous. Associated with pneumonia, severe sinusitis, severe acute polyarthritis, typhoid, pyemia, septicemia, encephalitis and meningitis (especially cerebrospinal). (*b*) Average temperature from 102 to 103 F. (*c*) Average duration from one to eight weeks and occasionally death.

3. Toxemias of great severity: (*a*) Disks with margins blurred by edema and vessels quite dilated. Surface of disks often fades insensibly into surrounding retina. White streaks show line of nerve fiber bundles. Occasionally retinal edema; punctate hemorrhages from the finer vessels into the retina. Twice small whitish, retinal areas around or near the disks were seen (retinitis septica of Roth?[2]). Occasionally edema of the disks was seen as a forerunner of a frank optic neuritis (1.5 per cent).

Table 1.—*Numerical Distribution of Fundus Changes*

		Class 1	Class 2	Class 3	Total of Each Disease	
					No.	%
Influenza and (grip?).........	105	29	..	..	29	16
Acute rhinitis.........	27	8	..	..	8	33
Sinusitis.......................	145	10	12	13	35	24
Pneumonia.....................	192	9	41	101	151	78
Acute multiple arthritis......	46	3	10	12	25	54

Encephalitis.....................	125	6	17	11	34	27
Meningitis: 1. Cerebrospinal..	22	..	9	7	16	72
2. Pneumococcic..	2	..	..	1	1	50
3. Tuberculous...	5	..	..	2	2	40
Cholecystitis with jaundice...	1	..	..	1	1*	
Total.......................	850	65	126	183	374	

* Percentage in cholecystitis is not significant because the other cases of jaundice were not tabulated. It is regarded in this series as an unusual complication probably due to the same focus causing the cholecystitis.

Table 1 shows the numerical distribution of these conditions.

ANALYSIS OF THE THREE CLASSES

Class 1 (18 per cent, 153): The mild types of the toxemias were, of course, in the minority, because the patients who apply for entrance into a general hospital have usually something more severe than a mild cold or uncomplicated influenza. Thirty per cent (forty-five) of the patients in this class presented changes ranging from slightly to moderately hyperemic disks. Hyperemia was called such only when the disks became less involved as the patient recovered. The fine grade of distinction between a normal and a hyperemic disk calls for a conservative reading. In 1901, von Michel reported two cases of septicemia with hyperemia of the disks which seemed to change during the course of the disease. An examination afterward revealed that both were normal. Terrien and Boudier[3] reported three cases of hyperemia of the disks in three cases of cerebrospinal meningitis.

Class 2 (56 per cent, 476): This type represented the largest class, but the next to the smallest percentage of changes. While changes here were not so striking as those in class 3, they were of sufficient definiteness to entitle them to consideration. Twenty-five per cent (119) of the cases in this group presented changes some time in the course of the disease. These changes consisted of increased capillarity of the disks, and occasional slight blurring of the margins, especially over the upper nasal border. The larger vessels, especially the veins, also had a tendency to become dilated, and, at times, slightly tortuous. Blurred disk margins never occurred in any patient with a temperature under 102 F.

Encephalitis	1	

Hirschberg[4] saw three cases of pneumonia with great hyperemia and slight edema of the disks, which had receded when he examined the patients after recovery. He definitely associated the phenomena with the toxic processes. Von Hippel[5] also reports papilledema in pneumonia, which disappeared after recovery.

Class 3 (26 per cent, 221): In this class are grouped the cases of severe pneumonia, meningitis, severe typhoid, septicemia and sinus diseases. Eighty-five per cent (190) in this group presented changes. One hundred and seventy-eight had various degrees of disk changes, ranging from increased capillarity to optic neuritis. Eighty-six presented a moderate edema of the disks, with slightly blurred margins and dilated vessels. Fourteen of these eighty-six had marked papilledema, which advanced with the progress of the disease and receded as the condition subsided. After recovery, the eyegrounds were entirely normal without sequelae. Thirty-two patients developed retinal hemorrhages. Twenty-six of these were of the finer punctate character, which were apparently from ruptured fine vessels. Table 2 shows the incidence of these lesions. Twenty-two patients in this group presented severe changes of one sort or another. Six developed optic neuritis, which appeared after the inception of the toxemia in each case. All developed the usual picture of visual disturbance and sequelae. Two developed embolism of the central artery; one, thrombosis of a branch of the central vein; one, a metastatic choroidal exudate; two metastatic choroiditis, and two, white retinal areas around the disks (septic retinitis?).

From the foregoing analysis it is evident that the severer types of infection produced the greatest percentage of lesions, both mild and severe. The cases that presented the simplest conditions, such as increased capillarity, slight edema of the disks, and retinal edema, associated with dilatation of the larger vessels (especially the veins), were of greater interest and of more importance than those which presented the severer lesions, such as hemorrhages, areas of degeneration, and neuritis. The former, if present, seemed to present a sort of bird's-eye view of the course of the disease, from which, quite often, could be told the stage and probable severity of the infection. All these signs seemed to be stages of varying degrees of the same process. The degree was usually found associated with the height of the temperature; i. e., the higher the temperature, the more pronounced the manifestations. In cases in which there was very mild involvement, such as uncomplicated influenza or not too severe pneumonia, nothing more than a mild hyperemia or dilatation of the larger vessels occurred. During the influenza epidemic of 1890, a great many ocular complications were reported. These are not to be confused with the changes noted here, for while the former are considered as complications dependent on accidental metastasis or communication, the latter are considered a part of the general reaction, returning to normal as the illness subsides.

In the severer toxemias (class 2), hyperemia was first manifested with dilatation of the greater vessels, and, if the process continued with an increased temperature (above 102 F.), edema of the disks often followed, which increased or subsided with the course of the disease.

The very severe infections, such as are represented in cases of severe pneumonia, encephalitis and meningitis, passed through the first two stages quickly and presented definite papilledema, retinal edema and, in certain instances, retinal hemorrhages and areas of degeneration in the retina. Observers of cases of meningitis differ widely in reports of ocular conditions. Randolph[6] found papilledema in 17 per cent. He also found retinal vein engorgement in nineteen out of thirty-five cases. Batten says that it is rare. Barlow and Lees[7] found three in forty-two cases. Twelmyer[8] reports a case of metastatic ophthalmia in cerebrospinal meningitis. Reports of papilledema and optic neuritis found in encephalitis agree essentially. The British

Government Board Report[9] states that papilledema in encephalitis is seen occasionally and optic neuritis exceptionally. Forty-seven patients examined by Moore[10] did not show changes referable to the disease. In the forty-eighth case there was secondary optic atrophy, but its cause was in doubt. I found one case of optic neuritis in 125 cases of encephalitis which was undoubtedly associated with the disease. Its entire course was followed from the beginning, which did not occur until a week after the admission of the patient. This patient died fourteen days after admission. I should like to repeat that such a condition was considered dependent on a secondarily infected optic nerve, while the simple edema is an altogether different affair associated with the general circulatory reaction.

Holden[11] mentions sinusitis as one of the causes of papillitis. Mention is not made of simple papilledema. In one case of severe pansinusitis in which there were acute symptoms of pain, headache and malaise, and a temperature of 103 F., the disks were markedly edematous, the vessels were quite dilated, and there was considerable retinal edema present, as shown by the regular waving of parallel vessels and an increased "watered silk" reflex. Drainage of the sinuses improved the condition, and the ocular signs gradually subsided until, some time after recovery, the eyegrounds were perfectly normal. A similar condition has been noted and discussed by other observers, but it has usually been explained as an isolated phenomenon instead of part of a generalized process. The cases which presented the severest general signs and in which the prognosis was ultimately bad presented the greatest fundus changes. Two cases of pneumonia passed through the ocular stages of hyperemia and edema, with later rupture of the finer capillaries, which produced widespread punctate hemorrhages. One patient passed through the earlier stages and finally developed bilateral optic neuritis. All three of these patients died. Bull[12] reported six cases of retinal hemorrhages in the course of pneumonia but did not record the outcome. Clothier[13] reports a fatal case of typhoid, in which the patient developed optic neuritis. The cases of retinal hemorrhages in the septicemias were in those of the severer variety; i. e., they were of longer duration, and more destruction and graver sequelae ensued. Flemming[14] reports forty-two cases and makes a like assertion. To avoid making this paper lengthy with interminable case reports, tables 1 and 2 have been prepared to show at a glance the incidence of the conditions.

I feel that the majority of these manifestations are due to local dilatation with increased permeability of the blood vessels and exudation into the surrounding tissues. I[15] reported similar conditions associated with serum sickness after the injection of diphtheria antitoxin. In these cases, the manifestations were associated with the increase and subsidence of the reaction, as indicated by the chills and the temperature.

Then, too, is it not true that it is fairly universally accepted that the great internal vascular beds, such as those in the abdomen and lungs, take part in a general dilatation with exudation during these toxemias, especially those in which there are severe symptoms and high temperature? This, with the contraction of the vessels of the skin, tends to hold heat in with a consequent elevation in temperature. Therefore, may not the retinal vessels take part in this general reaction? Their readily accessible position lends them importance, since they are the only vessels of consequence that can be so easily observed without undue manipulation.

The reports of similar conditions in toxemias indicate their probable occurrence but not their frequency or importance. The statistics compiled by different observers are at great variance. This is probably due to the fact that one observer may have examined each case only once and recorded his observations. Another may have examined his series only on consultation because the patients complained of ocular disturbance. The former would tend to report a very small percentage of changes and the latter would see only the very severe changes. These cases must be observed daily throughout the illness if the finer changes are to be noted and a basis for differentiation established of stages and severity of a given disease. Routine ophthalmoscopic examination of patients suffering from general illnesses is again emphasized, for, apparently, changes appear in the commonest diseases with sufficient regularity to make them of definite help in following the course of these diseases.

CONCLUSIONS

1. Ocular fundi in various types of acute toxemias present common changes, depending on the type and severity of the infection.

2. This appears to be a local manifestation of the general reaction.

3. The reactions in the main are simple hyperemia, slight dilatation of the larger vessels, and low grade edema of the disks and surrounding retina, associated with a greater dilatation, depending on the severity of the reaction.

4. There are other changes often seen occurring in the fundi in these diseases, such as retinal hemorrhages, whitish areas of retinal degeneration and occasionally papillitis.

5. The reactions described under 3 were considered to have occurred with sufficient regularity to entitle them to consideration as definite entities in these diseases, and consequently as of practical importance in diagnosis and prognosis.

2600 Union Central Life Building.

ABSTRACT OF DISCUSSION

Dr. James P. Fitzgerald, Chicago: Dr. Brown has presented for the first time the results of prolonged and painstaking observations on a series of cases of acute toxemia sufficiently large to permit a reliable correlation of data. The fact that certain features of fundus changes tend to become characteristic in diabetes, renal disease and high blood pressure has unduly limited the clinical application of ophthalmoscopic observations. To the experienced observer, the eyegrounds in meningitis, sinusitis, the pneumonias, and pericarditis are in a sense characteristic, too. The point of emphasis in this study is in the weight of its evidence that the bilateral eye conditions of the type described are the frequent and early and commonly disregarded first signs of systemic infection, and that cyclic variations in the eye picture run parallel to the fluctuating course of the disease. Predictability, with its support to the clinician, becomes possible on this basis. Furthermore, Dr. Brown has disclosed the only method by which ophthalmoscopy can hope to become clinically useful.

From the point of view of internal hospital administration as well Dr. Brown's work is demonstrative.

Administrative medical schemes in the past have favored team work between general and special services much less than they do at the present time, and the ophthalmologist has not always had facilities for following his cases through. The essential thing about the medical staff is that it shall form a cooperative group. The eye department especially is conceded such independence that it often operates as a special hospital within the general hospital.

The diagnosis of a choked disk in a lesion of the central nervous system brings out the interdependence of departments. A careful metabolism test and chemical examinations of the blood may be the first procedure in the treatment of many eye diseases. But persistent, asthenopic symptoms which might suggest an error in refraction or in muscle balance may vanish after a simple appendix operation, the removal of septic tonsils, or the elimination of other foci of infection.

Either chronic or acute septic and toxic conditions have a marked effect on the eye and are probably responsible for more indirect troubles than we recognize. Teeth, tonsils, bowel toxemias and focal infections generally, participate, and such nonbacterial toxemias as those which occur in pregnancy. Many different organisms are involved and the systemic effects may overshadow the local septic focus.

The eye is an intimate part of the body, not a solitary organ. The eye lesions in acute toxemias are closely dependent on constitutional conditions so grave as to overshadow the local condition.

A STUDY OF EXPERIMENTAL HEAT-STROKE *

W. W. HALL, M.D.
Lieutenant, M. C., U. S. Navy
AND
E. G. WAKEFIELD, M.D.
WASHINGTON, D. C.

A previous communication[1] presented a statistical study of heat injuries that have occurred in the United States Navy. The clinical aspects of heat injury and the several theories of its etiology, as given by various observers from biblical times until experimental work on the problem began with Claude Bernard, were cited.

In 1858, Claude Bernard[2] produced deaths in birds and mammals by raising their temperatures 4 or 5 degrees C., and showed that, at autopsy, the lesions found were similar to those noted in major heat-stroke. Bernard, in a later communication, considered the cause of death to be due to purely physical causes; i. e., elevation of the blood to such a high temperature. Following this work, in 1872, H. C. Wood[3] described some experimental studies. The conclusions drawn are practically the same as those of Bernard. Wood also noted that "the more violently a muscle is made to contract before subjection to heat, the sooner it becomes paralyzed." The fact that the production of heat and of lactic acid in muscle are both definitely increased by exercise probably had a bearing on this observation.

The formation of lactic acid during muscular contraction has been demonstrated and studied quantitatively by Hill.[4] Physiologists have shown that, in the resting muscle, lactic acid is present in only very slight traces (0.02 per cent), but the amount is greatly increased during contraction or in the processes leading to rigor.[5] Normally, two thirds of the lactic acid formed in the muscle during contraction is reconverted into glycogen. The remainder is oxidized, with the production of heat.[5] This acid is regarded as an intermediary product formed in the course of the chemical reactions constituting the normal metabolism of the muscle. Fletcher and Hopkins[6] have shown that, in heat rigor, a maximum of lactic acid is produced in the muscles (from 0.3 to 0.5 per cent).

Heat production, in the living organism, is brought about by oxidative processes, principally in the muscles. The heat production in the viscera is practically negligible.[7] Heat loss is accomplished by conduction, radiation, and evaporation of moisture from the body surface and from the lungs in the expired air, by introduction of cool fluids and foods, and through the various excreta. These physical processes, in turn, are influenced by the clothing, the temperature, humidity, and velocity of the air currents. It can be seen that, if the physical and environmental factors are altered, the organism must adjust itself physiologically to meet the given conditions. This adjustment is regulated by the so-called thermogenic center. Ott[8] observed that the introduction of a probe into the brain, puncturing the corpus striatum, caused an increase of temperature of the body which lasted for some time. However, lesions of the optic thalamus, septum lucidum, cortex, midbrain, pons and medulla have been stated to produce a general rise of body temperature. Barbour[9] has shown that heating the brain, by a special device, in the region of the corpus striatum produces a fall, and cooling, in this region, produces a rise in the body temperature. These experiments tend to show that there is a regulatory center in the brain which, if injured, produces changes in the body temperature. If such a center does exist, it would be likely that it played a very important part in major heat-stroke.

That the humidity of the air must, in some way, influence the production of heat-stroke is based on clinical observations. The long painstaking research of many observers, especially in obtaining wet and dry bulb temperatures (hygrometry) at the times of the greatest incidence of heat-stroke, have emphasized the fact that heat-stroke occurs in an environment in which the temperature is high with a high relative humidity.[10] Recently Flinn[11] exposed animals to "high dry" temperatures without disastrous results. Observations of Blagden and Fordyce,[12] in 1775, showed that a man in good health could stand, for a period of fifteen minutes, an exposure to a dry atmospheric temperature of 250 F. without feeling any ill effects or a serious rise in body temperature, while a beefsteak exposed at the same time to the same environment was cooked in thirteen minutes.

It is obvious that the body temperature of a mammal need only rise slightly above that registered by the wet bulb thermometer to lose heat to the surrounding

medium. Thus, in an environment of high temperature with a low relative humidity, the organism is efficiently cooled by rapid loss of moisture to the surrounding medium, while with the temperatures not nearly so high but with high relative humidity, the temperature (wet bulb reading) above which the organism must rise to lose heat to the surrounding air is such that great injury may be done.

In a disease which is either so acutely fatal or in which the imminent danger is soon past, it is not difficult to see why that which actually occurs just at the time of the injury has escaped notice. In 1863, H. C. Wood[13] observed that the blood of patients suffering major heat-stroke was of "acid reaction." The other information which has been obtained in the past from study of the patient actually suffering heat injury has taught us little with reference to the acute condition. The observations that have been reported are apparently the later result of the early injury. Gradwohl and Schisler[14] noted the parallelism between the urine and blood chemical reactions in heat cases and those of renal insufficiency. Myers and Lough[15] considered that retention of creatinine signified a grave prognosis (5 mg. per hundred cubic centimeters of blood). Gauss and Myer[16] observed numerous hyaline and granular casts in the urine on the second day. According to these observers, the total and differential blood counts are not remarkable. The white blood corpuscles ranged from 11,000 to 15,000. Dopter[17] states that there is a moderate increase in the number of cells in the spinal fluid. Many observers have studied the spinal fluid, among whom Hulbé and Pigache,[18] and Dufour[19] may be mentioned. The results agree in that the spinal fluid shows nothing remarkable.

That animals, especially the dog, horse and cow, are quite as susceptible to heat injury as is man has long been known and is well recognized by veterinary authorities.[20] However, the experimental production and study of heat-stroke in animals presented certain inherent difficulties. First, the ideal animals for such an experiment, horse or monkey, were, for us, out of the question. The dog is the only animal that is large enough to furnish sufficient blood to admit of the studies which were necessary without obscuring the clinical and pathologic changes by the loss of so large a quantity. The dog does not cool itself, as does man, by the evaporation of perspiration from the body surface, but, by panting, loses moisture from the mouth, tongue and throat. It would appear that this animal, having only this relatively limited area with which to cool the body, might be even more susceptible to heat injury than man. With this difference in cooling mechanism in mind and for the reasons stated, we chose the dog as our experimental animal. Our object was to produce experimental heat-stroke in dogs, and to study the essential pathologic change in the blood by chemical means. Autopsies were performed on a number of the animals, and the tissue changes observed.

A chamber for the production of experimental heat-stroke was constructed of pine lumber 1 inch in thickness, enclosing a radiator as a source of heat and insulated with asbestos and cardboard. In one end of the chamber, a glass door was made large enough to admit and remove the animal without difficulty. The door was large enough, therefore, to permit the animal to be observed during the experiment. An electric fan was placed in the chamber, opposite the animal. In the direct blast of the fan on the opposite side of the chamber were the thermometers (wet and dry bulb). The thermometers projected into the chamber through holes in the wall so that the bulbs were in the chamber and the temperature could be read on the outside.

In the chamber, as described, there was sufficient room to accommodate the animal during the experiment. The electric fan kept the air in constant motion, making "wet bulb" thermometer readings possible. The electric light facilitated constant observation. In order to produce the necessary humidity, a wet woolen blanket was spread over the radiator at the beginning of the experiment, and kept wet by a constant drip. Such an arrangement as this produced heat-stroke with great regularity; the appearance time of symptoms was, in general, proportional to the wet bulb reading. In some of the animals, individual susceptibility appeared to be a factor in the time of inception of heat-stroke.

The animals, at first, appeared comfortable, except for increased respiration. The premonitory symptoms of heat-stroke, if any, were a slowing and increased depth of respiration, restlessness, swelling and congestion of the eyes, and weakness of the legs. Occasionally, the first symptom was thirst. Several animals showed a generalized convulsive seizure. One of the animals showed tonic convulsive spasm of the legs (heat cramps?). All the animals showed loss of sphincter control and one a change in temperament. Severe diarrhea was noted for the first three or four hours in the animals which did not succumb early. The respiration became less frequent and, in those that died, very shallow before death. The rectal temperatures before the experiment varied from 102 to 103 F.; after the experiment, from 106 to 113.9 F.

The majority of our animals reacted following exposure with a typical "heat exhaustion" syndrome in that their temperature, which was very high (from 106 to 113.4 F.) following exposure, fell rapidly to a subnormal level, and rose only slowly during the next day in those that lived and then remained at the normal level. One animal (dog 7), which died five minutes after removal from the heat chamber and whose rectal temperature at that time was 109.4 F., had a rectal temperature at the time of postmortem examination (five minutes after death) of 113.9 F. This reaction is suggestive of a thermic fever syndrome. Another animal (dog 8) had a rectal temperature of 107.4 F. after exposure; fifteen minutes later, with the animal in a room temperature of 70 F., the rectal temperature had risen to 113.4 F. The temperature gradually fell to 100.4 F. within six hours after exposure, and the animal died twelve hours later. This reaction appeared typical of thermic fever.

Apropos of the common origin of the two types of symptom complexes, namely, thermic fever and heat exhaustion, the report of heat injuries on the U. S. S. *Kentucky* as given in the fleet surgeon's report[21] in August, 1918, is important. Dr. W. A. Bloedorn stated that following an accident to the draft ventilation of the fire room at the end of a full power run about twenty men and officers succumbed to the intense heat. Of this number there were about fifteen who had a subnormal temperature, cold, clammy skin, weak pulse —heat exhaustion—while about five had hyperpyrexia (up to 105 F.) and were delirious—thermic fever or sunstroke.

* No. 9 represents dog 6 exposed after two weeks interval.

METHODS

The samples of blood were obtained from the jugular vein after the neck had been shaven and the skin cleaned with alcohol. All the blood was drawn by venipuncture under neutral liquid petrolatum. The blood for p_H determination and carbon dioxide combining power of plasma was kept protected by oil; that for the other chemical procedures was placed in flasks, lithium oxalate (1 mg. per cubic centimeter) being used as the anticoagulant. Samples of blood were obtained as a routine before and after heat-stroke. Dogs used were short haired and of medium and small size. The ages were, as nearly as could be judged, from 1 to 2 years. Estimation of the nonprotein nitrogen constituents, sugar, chlorides and lactic acid were made on the tungstic acid filtrate from blood precipitated by the method of Folin and Wu.[22] Nonprotein nitrogen, urea and creatinine were estimated by the methods under the Folin-Wu system.[23] Blood sugar was estimated by the method of Folin.[24] Uric acid was estimated by the modified method of Folin,[25] using the Folin-Trimble [26] reagent. Chlorides were estimated by the Whitehorn method.[27] Plasma carbon dioxide combining power was estimated by the method of Van Slyke and Cullen.[28] Lactic acid was estimated by the method of Ryffel, as modified by Scott and Flinn.[29] Total solids of the blood were determined by the gravimetric method, and total blood nitrogen as a measure of total proteins by the Myers [30] method. Inorganic phosphorus was estimated by Benedict's [31] method. Calcium was estimated by the method of Tisdall.[32] The hydrogen ion concentration of serum was determined by A. B. Linden and L. E. Dawson of the Department of Agriculture, Bureau of Chemistry, using a potentiometer of L. E. Dawson's design,[33] and the quinhydrone electrode.[34] Blood serum was used for the p_H determination throughout so as to avoid any interference by the action of oxalate. The blood and serum were protected from contact with the air at all times, and during the process of centrifugalizing a one-hole rubber stopper was forced down in contact with the blood and plugged with a section of glass rod as recommended by Cullen.[35] Clean, neutral glassware was used throughout.

RESULTS

In analyzing the results obtained, as recorded in the table of averages (table 2) and in the detailed table (table 1), the most striking changes were those in lactic acid (chart 1) and in the alkali reserve as measured by the carbon dioxide combining power of plasma (chart 2). The average lactic acid in ten dogs before heat-stroke was 31.8 mg., all readings, except that in dog 2, falling between 21.2 and 35.4 mg. of lactic acid per hundred cubic centimeters of blood. The high lactic acid (53.1) and low plasma carbon dioxide combining power (31.5) found in dog 2 would indicate that the animal was not normal at the time of the experiment. The highest figure for lactic acid (194.7) and lowest level of carbon dioxide combining power (10.7) obtained were those found in the post-run specimen taken from this animal. The highest lactic acid after heat-stroke found in the other nine animals was 160 mg., and the lowest carbon dioxide combining power 20.6 (dog 3). There did not, however, appear to be an accurate correlation between the level of lactic acid and alkali reserve in the individual animals, as may be noted by reference to table 1.

Serum p_H dropped (hydrogen ion concentration increased) an average of 0.19 (seven observations). Here, too, there appeared to be no exact correlation between the change in p_H and the condition of the alkali reserve or lactic acid level. The definite swing toward the acid side noted in all the observations, as well as in the average, differentiates clearly the fall in alkali reserve from that of an acapnial process. The fact that Flynn's animals, which were exposed to high temperatures and low humidity, and whose respiratory rate was rapid over a much longer period of time, did not show a considerable fall in alkali, emphasizes this point. It may be noted that a panting dog, although it breathes rapidly to promote evaporation and cooling, breathes correspondingly less deeply and washes out less carbon dioxide, thus avoiding acapnia.

Blood sugar, as noted in the table of averages, increased 41 mg. It will be noted, however, by reference to table 1, that this was not a constant finding, and that, in a number of cases, the blood sugar was relatively unchanged, and in one case actually fell (from 118 down to 84). Note should be made that, in these experimental animals, the condition of heat-stroke was not complicated by a condition of physical exhaustion, as may be often the case in men at hard labor in whom carbohydrate store might be extensively called on for fuel needs.

Table 2.—*Experimental Heat-Stroke in Dogs: Average*

	Before	After	Increase	Decrease
Nonprotein nitrogen	42.8	57.0	15.0	....
Urea nitrogen	25.9	32.2	6.3	....
Uric acid	None	Trace (1)	Trace	....

Serum p_H	7.38	7.19 (7)	....	0.19
Inorganic phosphorus	4.15 (4)	3.56 (4)	....	0.59
Calcium	12.26 (3)	13.26 (3)	1.0	....
Total nitrogen	2.28 (3)	2.188 (3)	...	0.092
Total solids	18.5 (2)	18.45 (2)	...	0.05

Plasma carbon dioxide combining power expressed in per cent by volume; total nitrogen in grams per hundred cubic centimeters; total solids in per cent; other results (except p_H) expressed in milligrams per hundred cubic centimeters. Figures in parenthesis denote the number of observations on which results are based. Except where noted otherwise, this is ten.

Nonprotein nitrogen of the blood evidenced a constant, moderate increase. This was accounted for largely by the increase in urea nitrogen. Creatinine also was, uniformly, slightly increased. In dog 6, whose blood was examined after twenty-four hours, and again after two weeks following exposure (and charted as dog 9), the later manifestations of renal injury are most clearly brought out. The fact that in but one case was uric acid present in the blood (dog 9) is significant. In the normal dog, there is no uric acid in the blood. Mann [36] has shown that, in liver injury, the hepatic function first injured is that of uric acid destruction. The animal which showed presence of blood uric acid had been given heat-stroke twice in two weeks, and, it is reasonable to suppose, was manifesting liver injury beyond the ability of hepatic reserve to compensate wholly. The injury to the renal parenchyma is probably parallel to that of the parenchymal cells of and other viscera, noted in the tissue observations.

Inorganic phosphorus fell in each case observed, the drop averaging 0.59 mg. Were the acidosis, which was present, complicated by an acid phosphate retention, inorganic phosphorus of the blood should show an increase.

Calcium rose in two cases and remained constant in one, the average of three observations being a rise of 1 mg. This rise may perhaps be accounted for by a calcium mobilization by hydrogen ion increase.

Total nitrogen, as a measure of blood proteins (three observations, one not shown in table 1) showed an average fall of 0.092 Gm. per hundred cubic centimeters. Total solids (two observations, not recorded in table 1) fell 0.05 Gm. per hundred cubic centimeters or per cent. These changes in protein and total blood solids are slight and, in view of the possibility of experimental error in so small a number of observations, the safe conclusion is that no marked change in blood solids has been demonstrated.

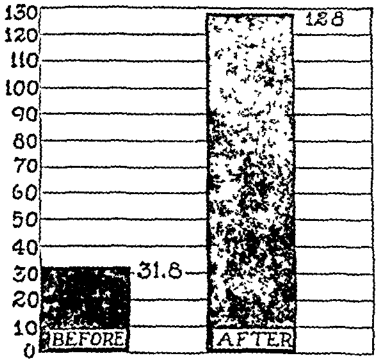

Chart 1.—Blood lactic acid in experimental heat-stroke.

Blood chlorides, calculated as sodium chloride, increased in all cases except dogs 6 and 9, in which a drop occurred. The average increase in the ten animals after heat-stroke was 26 mg. per hundred cubic centimeters.

Oxygen-combining power (two observations) remained normal. That is, hemoglobin estimation by the acid-hematin method of Newcomer[37] compared with the estimation of hemoglobin by the oxygen-combining power according to the method of Van Slyke,[38] showed no reduction by the latter method.

Specimens of urine were obtained from these animals after heat-stroke with some difficulty and in very small quantity. This apparent suppression of urine is in accordance with the clinical observations of H. C. Wood.[13] This condition is not difficult to explain when the acute degeneration, swelling and obstruction of the renal tubules are considered. Analysis of the urine showed much albumin, no sugar, and no ketone bodies (aceto-acetic acid and acetone). The absence of ketone bodies is of interest since it has been reported as an occasional finding in heat-stroke in man,[39] and a ketonic acidosis has been predicted in the condition.

PATHOLOGIC CHANGES

Gross.—Postmortem examinations were performed on a number of the animals. Some of them were examined immediately, and others from twelve to twenty-four hours after death. Nothing unusual was noted in the development of rigor mortis. The major change was rigid contraction of the left ventricle, and venous congestion of all the veins in the body, especially of the mucous membranes, lungs and liver. Except for a small amount of congestion of the meninges, there were no macroscopic changes in the brain and cord. The intestines were blanched and rigidly contracted. The stomachs were dilated and contained large quantities of fluid. The kidneys were of light color, and on section there appeared a marked cloudy swelling. The urinary bladder was often almost empty and tightly contracted. One animal (dog 3) showed petechial hemorrhages in the skin and mucous membranes. Several animals showed, in addition to pulmonary congestion, petechiae on the surface of the lungs, liver and spleen.

Microscopic (by Dr. E. E. Smith, United States Naval Medical School).—Pathologically, the tissues showed lesions consistent in type but variable in degree. In case of death early in the period of recovery, such as in experiment 2, the lesions were less conspicuous than in experiment 8, in which the animal survived the second exposure for twelve hours.

Morphologic disorganization of the parenchymatous cells was a characteristic feature of the tissues examined. This varied in degree from a fine, hardly detectable, granular degeneration to complete necrosis of both cytoplasmic and nuclear elements. There was practically no inflammatory response to this trauma except in the lungs, where edema was a striking feature, especially if death occurred late in the recovery period.

This degeneration was shown to occur in the heart, lungs, kidneys, intestines, liver, pancreas, spleen, thyroid and suprarenal; that is, in all the tissues removed for microscopic study. Of these the lungs, kidneys, liver, intestines and thyroid presented the greatest alterative changes.

Pulmonary edema was present in considerable degree in experiment 2, in which death occurred early in the recovery period. It was massive in degree in experiment 8. This edema was practically entirely interstitial in type, the alveoli being empty and constricted by pressure. The bronchial mucous membrane shared in the general parenchymatous degeneration and was covered with an extensive layer of material consisting of coagulated albumin and a few cells, chiefly necrotic epithelium.

Parenchymatous degeneration of the kidney occurred early and was extensive. It was of advanced degree in experiment 2, in which the convoluted tubules were primarily affected. In experiment 8 it was more advanced in extent and degree. In this case few lumens were patent and the glomeruli were shrunken instead of edematous as in experiment 2, while the capsules appeared distended as if under pressure.

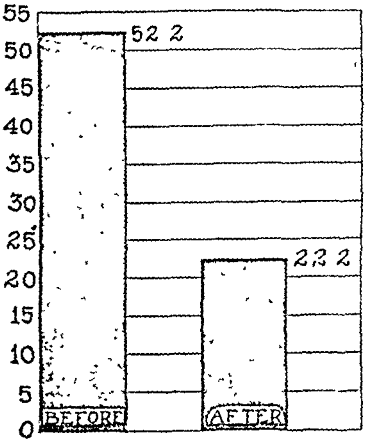

Chart 2.—Plasma carbon dioxide combining power (alkali reserve) in experimental heat-stroke.

The initial liver lesion was central and it varied in degree from a fine granular degeneration to complete necrosis. In experiment 2 it was more focal than in experiment 8. It was of milder degree than the necrosis found in acute yellow atrophy or in chloroform poisoning.

Necrosis of the epithelium was conspicuous in the intestinal tract. Sections from the colon revealed complete necrosis of the superficial layer of the mucosa, and an advanced degree of necrosis extended to the muscularis.

[39] Wilcox, W. H.: The Nature, Prevention and Treatment of Heat Hyperpyrexia, Brit. M. J. 1: 392-397 (March) 1920.

The thyroid appeared to suffer severe trauma during the recovery period. In experiment 2 it presented little alteration, while in experiment 8 there was extensive parenchymatous alteration. The majority of the acini were collapsed, and the cells were disorganized in arrangement and degenerated in structure. Some of the acini contained a pale colloid. The cells of these acini were cuboidal and showed degenerating protoplasm; many were separated from their basement membrane.

Accompanying this parenchymatous degeneration in all tissues was an acute passive congestion with deposition of blood pigment. This was of much greater degree in experiment 8, in which case it was accompanied by capillary hemorrhages.

NEUROPATHOLOGY

In brief, the neuropathology—microscopic study—by Dr. Walter Freeman, pathologist of St. Elizabeth's Hospital, was as follows: An advanced degree of parenchymatous degeneration was apparent in the brain. This degeneration was evidenced by a loss of concave outlines in the ganglion cells, a reduction of the chromatin to a hyaline, bluish staining material, a breaking up of the cytoplasm into small strands and vacuoles and, finally, a washing out of the cytoplasm. The nucleus tended to become more opaque than normal and to lose its sharp differentiation; in some instances it was displaced to the side of the cell. The nucleolus remained intact in all but the completely destroyed cells. The appearance of halos about the minute rounded glia nuclei was interpreted as swelling of the cytoplasm.

SUMMARY

Following exposure, the experimental animals reacted with the clinical syndrome of heat exhaustion as well as that of thermic fever, indicating the common etiology of these two types of reaction.

The blood chemical observations and pathologic changes in tissue following major heat-stroke showed that there was great renal injury evidenced by the progressively increasing azotemia in an instance studied twenty-four hours and two weeks after the injury. This nitrogen retention is obviously not a portion of the essential pathologic changes of the early acute condition. The uniform moderate increase in nonprotein nitrogen which occurred in the blood taken immediately following exposure is undoubtedly accounted for by rapid destruction of protein, incident to the high temperatures, increased metabolism and tissue damage. Nitrogen retention due to renal insufficiency would be impossible in so short a time.

Blood sugar increased in some cases, decreased in two instances, and remained relatively constant in others. That is to say, no significant or constant trend was noted in blood sugar level.

In most instances, blood chlorides increased. They decreased slightly in two cases, but the average showed an increase of 26 mg. per hundred cubic centimeters.

Alkali reserve, as recorded by plasma carbon dioxide combining power, decreased markedly in all instances, going as low as 10.7 per cent by volume in one case.

Lactic acid content of the blood reached very high levels following exposure, the increase averaging 96.2 mg. per hundred cubic centimeters, or an average increase of more than 300 per cent.

Serum p_H decreased (increase of acidity) in all cases in which the observation was made (seven) thus excluding an acapnial reaction in the fall of alkali reserve and emphasizing the uncompensated nature of the acidosis.

Total nitrogen and total solids determinations did not demonstrate any significant change in blood concentration.

Inorganic phosphorus of the serum was slightly decreased, and serum calcium showed an increase.

The pathologic changes were: rigid contraction of the left heart, venous congestion, contraction of the intestines and urinary bladder, dilatation of the stomach, and cloudy swelling and degeneration of the parenchymatous elements, particularly those of glandular and nervous character. There was no reaction of the connective tissue other than in the pulmonary changes noted.

CONCLUSIONS

*The important acute pathologic change in major heat-*stroke, other than that due to the effect of high temperatures per se on the tissues, is a massive increase in lactic acid, with the resulting symptoms of acidosis.

PERORAL ADMINISTRATION OF COLLOIDAL CONTRAST MEDIUM IN CHOLECYSTOGRAPHY

BERNARD FANTUS, M.D.
CHICAGO

The substances used at present for the purpose of cholecystography are derivatives of phenolphthalein, with which they share many of its qualities. This body, a white, insoluble powder, owes its use as an indicator of free alkali to the fact that it forms brilliant red soluble salts on the addition of alkali. That it also has purgative qualities was discovered when, almost thirty years ago, the Hungarian government decreed that wine, adulterated by certain harmless additions, be earmarked by means of phenolphthalein so as to enable the poor man to buy this "necessity of life" at a price within his means. It was soon found that people partaking freely of this wine suffered from diarrhea, which led to a hasty repeal of the law and the discovery of a new purgative. Vamossy,[1] who subsequently investigated this matter, found that phenolphthalein is but little absorbed from the gastro-intestinal tract, quite devoid of toxicity, and can safely be used as a cathartic.

With the hope of possibly finding a serviceable hypodermic purgative, Abel and Rowntree[2] experimented with a number of derivatives of phenolphthalein, among them the tetra compounds with chlorine, bromine and iodine. These bodies are, like phenolphthalein, odorless and tasteless white crystalline substances, insoluble in water, and quite nonirritant when applied locally. With alkalis they form deeply colored salts (hereafter to be called "dye") that are highly irritant. This is due to the fact that they are very weak acids, even carbonic acid precipitating them, and that, when combined with a powerful base, they are strongly hydrolyzed in aqueous solution. Hence they act on tissues like solutions of caustic alkalis. When such solutions are injected subcutaneously, even though they are sterile and isotonic, necrosis of fatty tissue results. Oil suspensions of the insoluble phthaleins are better borne hypodermically but rather slowly absorbed.

[2] Abel, J. J., and Rowntree, L. G.: On the Pharmacological Action of Some Phthaleins and Their Derivatives, with Special Reference to Their Behavior as Purgatives, J. Pharmacol. & Exper. Therap. **1**: 231 (Aug.) 1907.

That the phenolphthaleins have no antiseptic action is shown by the fact that luxuriant bacterial growth may be obtained on culture mediums containing them. Bile containing these bodies in abundance is not bactericidal.

When the soluble salts are taken into the stomach, they are quite irritant and usually promptly evacuated by emesis. The insoluble tetrahalogen derivatives of phenolphthalein, on the other hand, are quite well borne by the stomach, practically not absorbed, and have a purgative action like phenolphthalein.

These bodies have no effect on blood; they do not produce hemolysis nor do they cause changes in coagulability when injected intravenously suspended in serum. It is evident that excessive quantities of the soluble salts added to blood will have the effect of free alkali.

Animal experiments have shown that the arterial blood pressure is lowered only when these drugs are injected into the blood stream with undue rapidity, and even in that case the fall is of the most transient character. A slight rise of arterial pressure is caused by the presence of large quantities of the drugs in the vascular system.

In human beings, slow intravenous injection of the soluble salt generally does not produce any effect on the circulation. The blood pressure remains practically unchanged; and absence of effect on the heart has been demonstrated by Reid and Kenway[3] by means of the electrocardiograph. Not infrequently "reactions," sometimes of most alarming nature, are experienced, consisting most commonly of a feeling of nausea, usually unattended by vomiting. Less commonly there occurs vasomotor collapse of various degrees of severity, with pallor, palpitation, prostration and perspiration, which may be preceded by extreme redness of the skin. These effects are erratic in their occurrence, probably akin to those liable to follow any intravenous injection, and possibly due to what the French call a "colloidoclastic" crisis. This is also suggested by the fact that epinephrine seems to be of analeptic value in these as in other similar reactions.

Abel and Rowntree[2] found that, while in the system, these phthaleins exert no demonstrable action; nor do they produce, after repeated injections, evident degenerative changes, even in the liver, which seems to have most to do with the elimination of these bodies.

More recently, Ottenberg and Abramson[4] have shown experimentally in animals that these bodies are capable of producing lesions in the liver; but the doses required are from four to six times larger per kilogram of body weight than the doses used for cholecystography in man.

In the course of their study with these phthalein derivatives, Abel and Rowntree[2] discovered the remarkable fact that the only channel for the excretion of the tetrahalogen derivatives is the bile, the amount that passes into the intestine in other secretions, into the urine, or into the milk being so minute that it cannot be detected. In this respect these compounds differ markedly from phenolphthalein, which is excreted to a considerable extent by the kidneys. These investigators also discovered that a single subcutaneous injection of tetrachlorphenolphthalein (0.4 Gm.) dissolved in oil (20 cc.) acted as a laxative for as long as four or five days. This they explained by the observation that it is reabsorbed, from its solution in bile, by the large intestine, as can be shown by the red coloration the mucosa of the colon assumes when treated with alkali. This reaction cannot be obtained in the mucosa of the small intestine. That portion of the drug which is absorbed by the large intestine is again excreted by the liver, and again absorbed in large part by the mucosa of the colon, with a repetition of this cycle as long as the drug remains in the system. From four to five days after subcutaneous injection it may still be detected in the feces. Its low solubility in oil, necessitating a large bulky injection, stands in the way of the general adoption of this as a hypodermic cathartic.

Because of its specific elimination by the liver, tetrachlorphenolphthalein was proposed by Rowntree as a liver function test, and its value studied clinically by him and collaborators[5] and experimentally by Whipple, Peightal and Clark,[6] with results that established the almost complete elimination of this substance by the liver in normal human beings, and its delay in cases of diffuse liver disease.

This work of Abel and Rowntree offered the suggestion to Graham and Cole that the gallbladder might possibly be rendered opaque to the roentgen rays by the bile containing some such dye. The chlorine derivatives having been found unsatisfactory, and, as opacity to the roentgen rays is proportional to the atomic weight, they tried the bromine and iodine derivatives, because bromine is more than twice as heavy as chlorine, and iodine almost four times as heavy. The iodine derivative was at first found too toxic and unstable, and the bromine derivative was advocated by Graham and his collaborators.[7] Improved methods of manufacture and preservation have, however, established the iodine derivative as superior[8] because efficient in smaller dose. The mere elimination of the dye by the bile is not sufficiently satisfactory for visualization of the gallbladder. It is because this organ is not only a storage place for bile but also capable of concentrating it that it becomes sufficiently opaque to cast a fairly dense shadow.

Copher[9] has shown that the halogen in the bile is concentrated from two to four times by the gallbladder. To permit this concentration to occur, it is necessary for the bile to remain in the gallbladder for quite a number of hours. Therefore this viscus must be kept from emptying itself, which may be accomplished by not permitting any food to enter the stomach until after satisfactory pictures have been obtained, which is generally within from twelve to sixteen hours. Indeed, the prompt disappearance of the shadow after a meal rich in fat is one of the criteria of a normally functionating gallbladder; namely, its emptying power. So is the diminution in size of the shadow and its increasing density during the time the dye remains in the gallbladder, which shows that the concentrating power is still there, a function lost in cholecystitis.

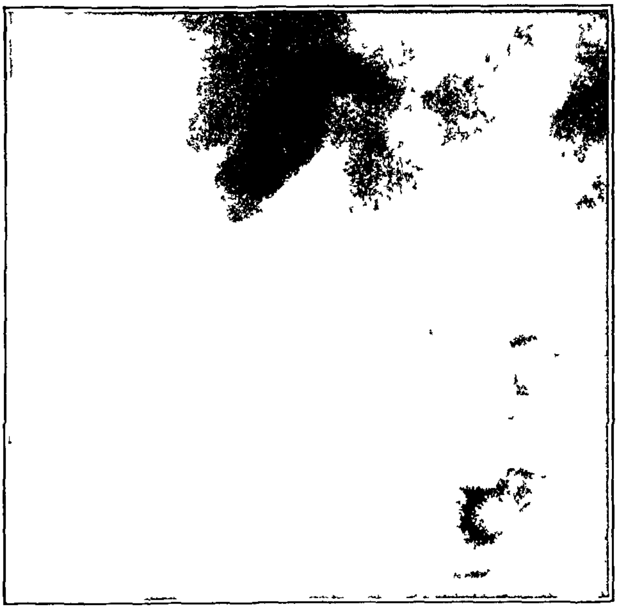

Fig 1—Appearance twelve hours after peroral administration of solution of tetraiodophenolphthalein to man, aged 47 Shadow in hepatic flexure of colon shows presence of excess of dye

The intravenous injection advocated by Graham presents the disadvantages of pain and troublesomeness of administration; of disagreeable reactions, such as headache, dizziness, nausea or vomiting; weakness; diarrhea; pain in the back or abdomen; chills, and "smothering" or "nervousness" in from one third to two thirds of all administrations.

There is a liability to venous thrombosis, as well as to necrosis of the skin overlying the vein on paravenous injection. One death followed the intravenous administration of 5.5 Gm. in one dose, almost twice the dose recommended. Giving the dose in two injections instead of one is advocated, to make the procedure safer and less liable to undesirable reactions.

Of late Graham and his collaborators[10] are using the sodium salt of phenoltetraiodophthalein, an isomer of tetraiodophenolphthalein, by intravenous injection for cholecystography. They obtained satisfactory shadows of the gallbladder with smaller doses (2.5 Gm. for adults) and have had fewer (35 per cent) and less severe toxic reactions. This substance seems to be more rapidly secreted by the liver. Excellent shadows of the gallbladder may be obtained four hours after injection, so that the time necessary for a cholecystographic examination can be shortened. They also find that this salt stains the serum sufficiently after alkalization to permit quantitative estimation, thus making it possible to perform a liver function test in addition to a cholecystography.

ENTERIC ADMINISTRATION

Peroral administration, which would be quite advantageous from a clinical standpoint, presents considerable difficulty. The dye is changed by the acid of the stomach into a white, sticky mass, quite difficult of solution, therefore inert as far as obtaining shadows of the gallbladder is concerned, and yet having quite a tendency to cause nausea and vomiting.

Menees and Robinson,[11] Stewart and Ryan[12] and others attempted to solve the problem by enteric administration, even to the extent of introduction directly into the intestine by means of a duodenal tube. Rectal injection has also been resorted to[13] of concentrated solution as well as the dilute solution in the form of a drip, but abandoned, even though gallbladder shadows were obtained, because it is poorly tolerated. All possible methods of enteric encapsulation have been tried: formaldehyde-hardened gelatin (Menees and Robinson), coating with phenyl salicylate (Whitaker, Milliken and Vogt[14]) and keratin coating (Stewart and Ryan).

Though none of these is entirely satisfactory, and Graham and his collaborators still cling to the intravenous injection as the method of choice, enteric encapsulation has established itself as the routine practice with many roentgenologists, who reserve intravenous administration for those cases only that do not yield unequivocal results after the giving of the capsules.

One of the difficulties of enteric encapsulation is that the capsules may open in the stomach and produce nausea and vomiting, or else that they may not disintegrate at all or promptly enough to yield the dye to

absorption. As good gallbladder shadows are frequently obtained in spite of the fact that quite a few of the capsules have remained undissolved, it is evident that, with peroral administration, we are using an excess of dye. Menees and Robinson [11] find 2.5 Gm. a satisfactory minimum; and since perhaps half the dose is never absorbed, as shown by the shadows in the colon, gallbladder visualization must be produced by a smaller quantity of dye given perorally than when it is given intravenously. For, on peroral use, the phthalein derivative is brought directly to the liver by the portal vein without being carried all through the circulation and spread all over the body, as it is on intravenous injection. A serious objection, it seems, to enteric encapsulation is the opening up of the capsules and the possible discharging of their very irritative contents, in concentrated form, against the mucosa of the bowel with possible damage. No wonder that some patients complain of nausea, or that some are purged or have abdominal colic or backache, after the giving of the capsules. Should purging be produced to such a degree as to vitiate the result, recourse to intravenous injection may still not be necessary, if one gives a 0.06 Gm. capsule of powdered opium along with the dye capsules, repeating the dose in from two to four hours if required. It might not be altogether fanciful to imagine that these hard and insoluble capsules might be forced by peristalsis against a peptic ulcer with resulting pain and even possible perforation. In one of my patients with duodenal ulcer, these capsules did produce so severe an attack of abdominal pain that hypodermic injection of morphine and atropine became necessary.

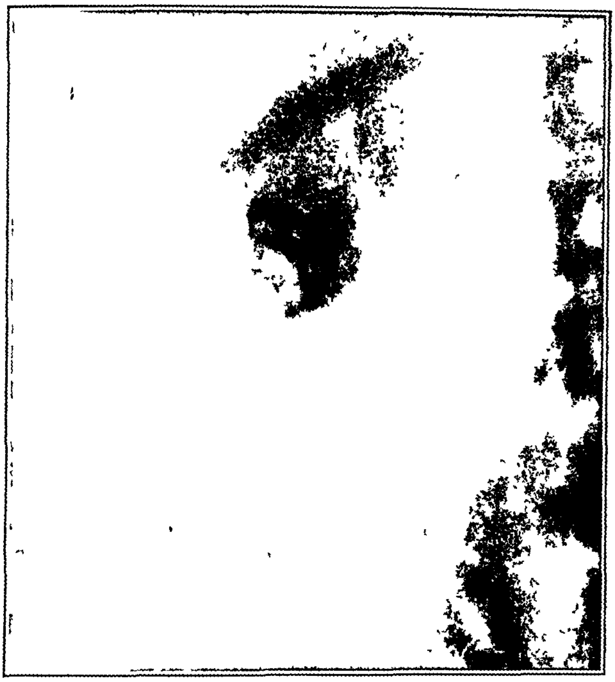

Fig. 3 —Large pale gallbladder shadow with cluster of faceted stones in fundus, twelve hours after peroral administration of solution to obese woman.

PERORAL ADMINISTRATION OF SOLUTION

For these reasons, and also because patients are occasionally encountered who cannot or will not swallow capsules, it seemed worth while to undertake experiments to determine whether the dye may possibly be given by mouth without encapsulation. The situation seemed to present two aspects: first, reduction of the alkali irritation produced by the soluble dye salt, and suppression of the emesis; and. secondly, protection of the dye against precipitation by the acid of the gastric juice. To reduce alkali irritation, the minimal effective dose had to be determined. This is below 2.5 Gm. for an adult, for giving the agent in solution is more effective than capsule administration in yielding the dye to absorption, as has been proved. Possibly the smaller dose of phenoltetraiodophthalein might be of sufficient advantage to make it preferable for oral use, in spite of its at present apparently excessive price. This dose was given in a glassful of demulcent vehicle. Milk suggested itself, for, to the extent to which its protein and its emulsified fat are attacked by the alkali, it will protect the mucosa against irritation. We must, however, get the milk out of the stomach, as the longer the milk stays in the stomach the more hydrochloric acid must be neutralized. I have tried sodium citrate (1 per cent) to prevent curdling of the milk, with but partial success. Cream and water, equal parts, is probably a better vehicle. The dose was given just before the patient went to bed for the night, after he had partaken of a very light meal four or five hours previously.

To neutralize the gastric juice is not an easy task, as is well known. I have made the attempt by giving an alkali powder composed of sodium bicarbonate, 1 Gm., and precipitated calcium carbonate, 2 Gm., in a wineglassful of water just before the dye is administered in cream and water. As the stomach has a great tendency to overcome this artificial depression of acidity, it is necessary to give alkali at intervals afterward. I have given an alkaline powder every half hour after the first one, until the patient is asleep.

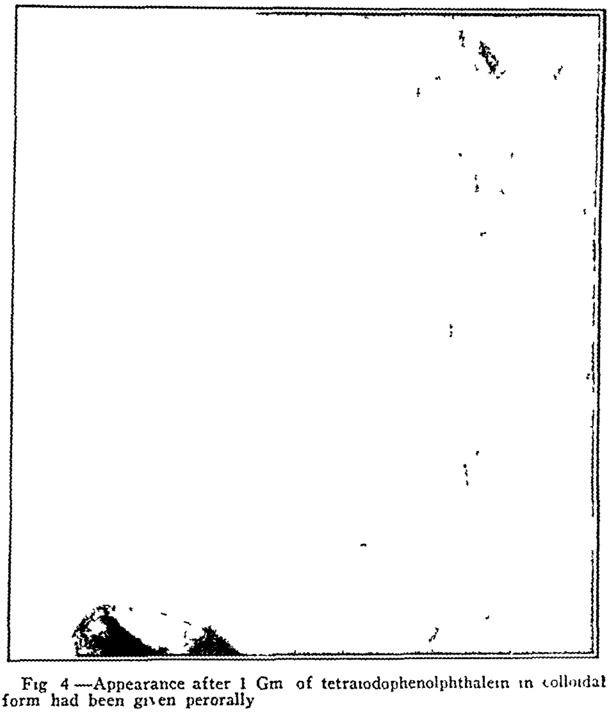

Fig 4 —Appearance after 1 Gm of tetraiodophenolphthalein in colloidal form had been given perorally

From my experience with the process, as described, I have no hesitancy in asserting that it works, as may be shown by a few of the cholecystograms (figs. 1, 2 and 3) I have obtained in this manner from twelve to sixteen hours after giving the dye. Vomiting, which occurs in a certain number of cases, was still the chief difficulty. Even when vomiting occurred, it was usually so late that the dye was sufficiently absorbed to permit gallbladder visualization. My experience justifies agreement with the statement of other students of the subject that, if the dye is retained for more than one hour and even less, the gallbladder can be visualized in all normal cases.

One reason for a high incidence of emesis in cholecystography, no matter by what method the dye is introduced, is that most of the persons subjected to this examination suffer from gastric disturbance and that quite a proportion of them are prone to nausea or vomiting even after the ingestion of ordinary foods. In cases, therefore, in which a tendency to vomiting is known to exist, it might be well to forestall emesis by administering, half an hour before the first alkaline powder, a dose of hypnotic, e. g., phenobarbital sodium, 0.3 Gm., so as to secure a night's good sleep. To forestall purging, a dose of powdered opium (0.06 Gm.) might also be given. Fortunately, it has been possible to eliminate the tendency to emesis almost entirely by administration of the agent in colloidal form.

ADMINISTRATION IN COLLOIDAL FORM

Test tube experiments show that, when sodium bicarbonate is added to the dye solution, a precipitate occurs, most of the tetraiodophenolphthalein being thrown down in the form of very fine particles. Yet this suspension gives fairly satisfactory shadows. It is therefore not necessary to attempt maintaining the dye in solution. One may indeed doubt, in view of the ease with which the dye is precipitated by carbonic acid and the abundance of this body in the system, whether the dye is not first precipitated before it becomes active, no matter in what form and by what channel it is administered. It then occurred to me that it would be worth trying to give the contrast medium in the form of a very fine precipitate, preferably colloidal, so as to secure maximum solubility in the solvent juices of the intestine. This I have accomplished by the addition of carbonated water to the dye solution, or by passing a stream of carbon dioxide through it until it is discolored. To stabilize this colloidal precipitate, a protective colloid is desirable, which not only keeps the fine precipitate in suspension but also prevents its deflocculation in coarse, curdy form by such influences as the gastric juice. A very dilute tragacanth mucilage has been found satisfactory for this purpose. This mixture looks like milk, is not offensive to the taste, and is sufficiently well borne by the stomach not to cause emesis. This colloidal contrast medium can, no doubt, be elaborated in solid form by a process analogous to the one by which the colloidal silver preparations are produced, and might then be given in ordinary gelatin capsules without the liability to gastric or intestinal irritation inherent in the soluble dye.

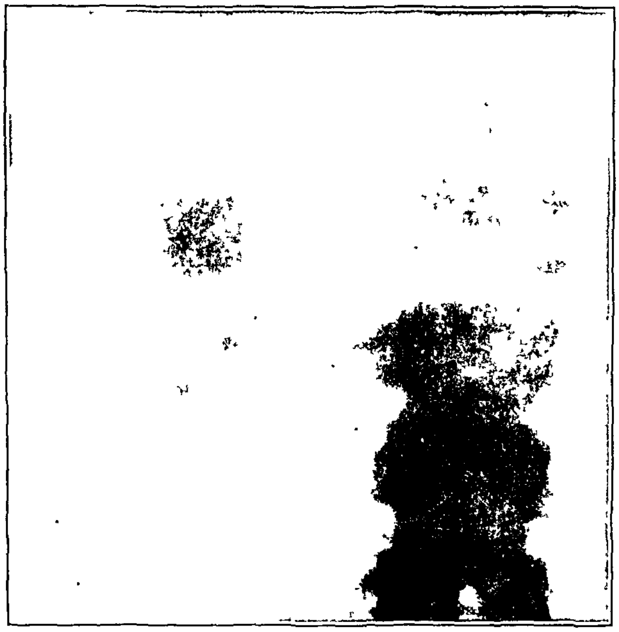

Fig 5.—Shadow obtained after 2 Gm of colloidal medium when 1 Gm. failed (Mrs. S).

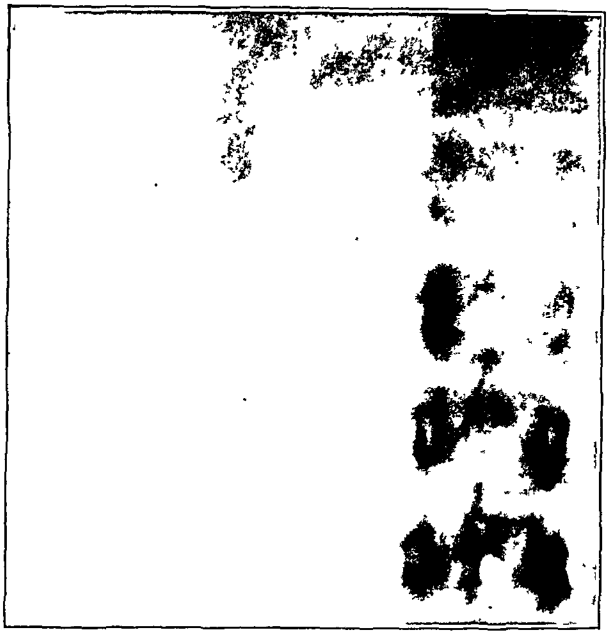

Fig 6.—Same case as figure 5 one hour after a meal, showing that gallbladder is not well emptied

That the solubility and absorbability of the agent has in this manner been increased is shown by the fact that as little as 1 Gm. of the dye gives a shadow in a normal person (fig. 4). I found, however, a case in which 1 Gm. failed to show a shadow but 2 Gm. did (fig. 5). That this is probably a pathologic gallbladder is indicated by the fact that the shadow did not disappear soon after a meal, as it normally does (fig. 6). Though 3 Gm. is as well borne as a smaller dose, it is probably not necessary to give more than 2 Gm., as I found that when 2 Gm. did not give a shadow 3 Gm. also failed.

The preparation advocated renders cholecystography very simple. The subject is advised to eat an early light supper and to take the mixture just before retiring, say at 9 or 10 o'clock. The next morning, if the person has not ingested any food in the meantime, one will in a normal individual obtain a rather faint cholecystogram, which becomes much denser by the sixteenth hour and disappears shortly after a meal. So simple is the process that it should be possible to perfect a technic by which cholecystography may be introduced as a routine into the gastro-enteric roentgenographic series, as I have recently done. By such a combination we have actually photographed the gallbladder and the bile ducts in the act of emptying into the duodenum.

What remains to be done is to study, in the first place, means of intensifying the shadow to the maximum degree possible, though the procedure as I now have it gives fairly good results. As absorption of the contrast medium probably occurs only in the proximal colon, keeping the contents of this portion of the intestine in a liquid state should be favorable. As alkali aids in the solution of the precipitate, increasing the alkalinity of the bowel might also be desirable. With these considerations in mind, I have been giving a teaspoonful of a mixture of 1 part of sodium bicarbonate and 2 parts of sodium phosphate in a cup of hot water half an hour before meals, including the last supper. Giving magnesia might be a still simpler means to the same end. Possibly the administration of bile might help solution and absorption of the agent. Phenoltetraiodophthalein might be superior to the dye I employed; but its present price is almost prohibitive.

Another problem that requires elucidation is what besides pathologic conditions of the gallbladder interfere with adequate absorption. Such, for instance, exists when the cecum and colon are packed with retained fecal matter, as in cecal stasis. Preliminary purgation, as suggested, should take care of such interference.

Even in the present state of the experiments it may be concluded that the problem of peroral cholecystography will probably be solved by the administration of the contrast medium in colloidal form.

ULTRAVIOLET RADIATION FROM SUNLIGHT AND INCANDESCENT LAMPS

ITS TRANSMISSION THROUGH WINDOW GLASS AND SUBSTITUTES *

HERMAN N. BUNDESEN, M.D., Sc.D.
HARVEY B. LEMON, Ph.D.; I. S. FALK, Ph.D.
AND
E. N. COADE, M.S.
CHICAGO

In a recent report on window glass substitutes, the Council on Physical Therapy of the American Medical Association[1] presented the results of investigations which "encourage the belief that there are now available materials for glazing our windows which do not possess the fault of window glass in excluding the health-giving rays of sunlight." We present here a preliminary report on experiments that were started about a year ago. Our studies were designed to cast some light on the relations between seasonal variations in ultraviolet radiation from the sun and seasonal incidences of morbidity and mortality. In addition to obtaining, under the supervision of Prof. Henry G. Gale and Prof. A. J. Dempster, daily spectroscopic records of Chicago's sunlight and records on other meteorological conditions, we have obtained some data which may be of interest to readers of The Journal at this time.

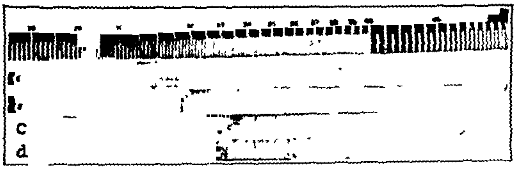

Fig. 1.—Absorption of ultraviolet rays by smoke: *a*, 11 a. m., April 10, 1927; wind nortneast; very clear. *b*, 10:30 a. m., February 19; wind northeast; very clear. *c*, 3 p. m., February 19; wind northeast; very clear, but sun seen through smoke from the stockyards district. *d*, 2:45 p. m., February 23; wind southwest; clear; sun seen through smoke. Short wave length limit: *a*, 2,995; *b*, 3,030; *c*, 3,090; *d*, 3,090.

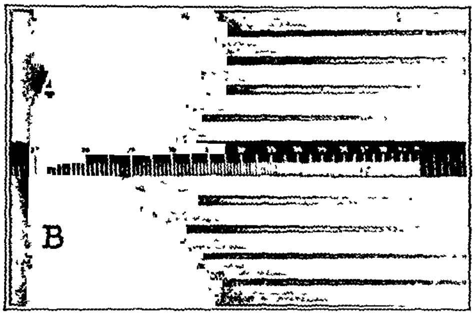

Fig. 2—Spectrums for incandescent lamps (from five to eighty second exposures); 300-watt gas-filled lamps: series A, ordinary glass bulb; series B, Vitaglass bulb.

* It should be noted that the measurements presented in this table agree very closely with those given in figures 1-6 where the records apply to the same days, although the data in this table are from plates taken with a diffraction grating and the photographs reproduced in the illustrations were taken with a quartz spectrograph.

In June, 1926, experiments were begun to arrange apparatus for the automatic recording of the sun's spectrum. Each day a photograph of the solar spectrum is taken on a portrait film. The photographs are calibrated by exposing them behind a uniform optical wedge for a fixed time to a light of fixed intensity. They are then developed in carefully measured solutions for a fixed time and at a fixed temperature. (The details of technic will be reported later.)

---

* From the Department of Health, City of Chicago, and the University of Chicago.

[1] Report on Window Glass Substitutes, J. A. M. A. 88:1562 (May 14) 1927.

In the accompanying table we present the limits of the solar spectrum in Chicago on certain days between Nov. 28, 1926, and May 16, 1927. For the periods November 28 to December 8, December 12 to 14 and December 16 to 28, the data are for the spectrums on successive days. For the period January 15 to May 16, we present the spectrum limits for that day in each week which, judged from weather bureau reports on wind and sunshine, was the clearest. Thus, in large part the data in the table were taken from plates selected to show most favorably the extreme spectrum limits in the ultraviolet region.

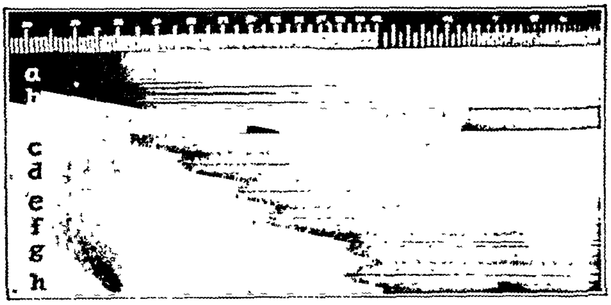

Fig. 3.—Transmission of sunlight and light from incandescent lamp through quartz and Vitaglass:

	Short Wave Length Limit
a, Sunlight through quartz: 30 seconds	2,995
b, Sunlight through Vitaglass: 30 seconds	3,010
c-h, light from 300-watt Mazda C lamp through Vitaglass	
c, 80 seconds	2,760
d, 40 seconds	2,790
e, 20 seconds	2,860
f, 10 seconds	2,960
g, 5 seconds	3,050
h, 2 seconds	3,140

From direct inspection of the original plates it is plainly evident that the solar radiation reaching Chicago in the winter months is extremely poor in the spectrum region 3,200 to 2,900 angstrom units. Under the most favorable conditions, the last detectable lines are in the region of 3,100 to 3,050 angstrom units in November, December and January and are of extremely low intensity there. In February, March and April the limits are in the region 3,040 to 3,000, and by May the limit is reduced to 2,990. These results are especially significant because of the recent observations of Hess and Weinstock.[2] These investigators report that the spectrum line at 3,020 angstrom units possesses marked antirachitic potency; the 3,130 line only very slight specific power to activate cholesterol; and lines of wave length shorter than 3,130, especially those shorter than 2,900 angstrom units exert even more potent antirachitic activating effects on cholesterol than those between 3,020 and 2,900.

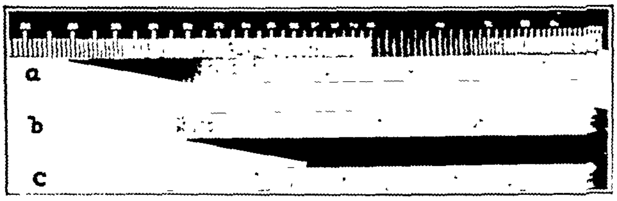

Fig. 4.—Transmission of sunlight through quartz, clear Vitaglass and laboratory window, 9:30 a. m., Feb. 19, 1927: wind northeast; very clear. *a*, clear Vitaglass, 3,090 angstrom units limit; *b*, quartz, 3,050 angstrom units limit; *c*, laboratory window, 3,300 angstrom units limit.

On a number of occasions it has been feasible to study the effects of smoke in the city's atmosphere on the solar ultraviolet radiation. In March, when Chicago's atmosphere is commonly heavily laden with smoke, we have found that the solar spectrum usually does not show any appreciable light intensity below 3,100 angstrom units. Figure 1 presents for comparison the solar spectrums on:

(*a*) A clear day, April 10, 1927, with wind northeast (from Lake Michigan).

(*b*) A clear day, Feb. 19, 1927, with wind northeast, 10:30 a. m.

(*c*) Same day as *b*, at 3 p. m., with identical sky and wind conditions except that the afternoon sunlight path to the spectrograph traversed the smoke pall arising from the stockyards manufacturing district.

(*d*) A clear day, Feb. 23, 1927, with wind southwest and a smoke haze over the city.

It will be observed in figure 1 that on a clear day in April the sun's spectrum extended down to about 3,000 angstrom units. On February 19, clear, the spectrum limit was 3,030 angstrom units. The reduction of the spectrum limits by smoke, expressed in intensity, is much greater, however, than the change of 60 angstrom units in the limits would imply.

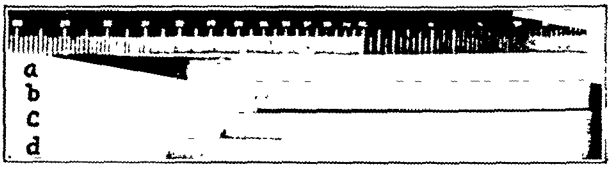

Fig. 5.—Transmission of sunlight, Feb. 19, 1927, through: *a*, quartz, 3,030 angstrom units limit; *b*, laboratory window, 3,280 angstrom units limit; *c*, thin glass, 3,230 angstrom units limit; *d*, quartz, 3,030 angstrom units limit.

Because of the comparatively feeble ultraviolet intensities in the sunlight of the winter months, it was considered important to study certain artificial sources of ultraviolet radiation. The value of the mercury vapor arc lamp is too well known to need demonstration here. But the value of ordinary incandescent lamps has not been sufficiently investigated. Figure 2 presents the spectrums (for five, ten, twenty, forty and eighty second exposures) of the radiations from 300 Watt gas-filled Mazda lamps, one (upper series) with ordinary glass bulb and the other (lower series) with a bulb of Vitaglass (Lamplough). It will be noted in figure 2 that the lamp with the ordinary glass bulb emitted ultraviolet radiation comparable to sunlight in the winter months. The Vitaglass lamp was far richer in transmitted ultraviolet rays, the eighty second exposure detecting radiations as far as the region of 2,800 to 2,900 angstrom units.

From figure 3 it is apparent that clear Vitaglass[3] transmitted the ultraviolet rays in sunlight nearly as well as quartz. Furthermore, with a Mazda C lamp (300 watts) as a source of illumination, Vitaglass (eighty second exposure) transmitted the ultraviolet rays as low as 2,760 angstrom units.

[2] Hess, A. F., and Weinstock, Martha: The Antirachitic Activity of Monochromatic and Regional Ultraviolet Radiations, Proc. Soc. Exper. Biol. & Med. **24**: 759 (May) 1927.

[3] Sample provided by the Vitaglass Corporation, New York.

Figures 4 and 5 present some transmission spectrums for sunlight passed through quartz, clear Vitaglass, the laboratory window glass and a piece of thin window glass. The advantages of Vitaglass over ordinary glass are plainly evident in the greater ultraviolet transmission permitted by the former.

Figure 6 presents comparison spectrums for the transmission of sunlight through quartz, clear Vitaglass and a sample of M. G. Co. glass.[4] The two window glass substitutes tested here gave almost exactly the same results, both transmitting the sunlight available on the day of the test to 3,000 angstrom units.

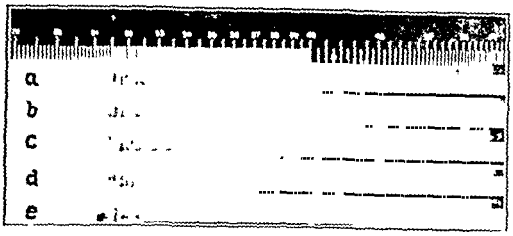

Fig. 6.—Transmission of sunlight, June 1, 1927, 3 p. m.; exposures, thirty seconds; wind, north; slit, 3.5; very clear; through: *a*, M. G. Company glass, 1.9 mm. thick, 3,000 angstrom units limit; *b*, quartz, 2,980 angstrom units limit; *c*, clear Vitaglass, 2 mm thick, 3,000 angstrom units limit (faint); *d*, M. G. Company glass, 3,000 angstrom units limit; *e*, quartz, 2,980 angstrom units limit.

SUMMARY AND CONCLUSIONS

1. *Comparatively little ultraviolet radiation of known physiologic significance appears in the sun's spectrum during the winter months in Chicago.*
2. The ultraviolet rays are absorbed to a significant degree by smoke in the atmosphere.
3. Incandescent lamps (of 300 watts) emit radiations in the ultraviolet region which are of physiologic interest.
4. Transmission spectrums for window glass and certain window glass substitutes confirm the reports of other investigators and of the Council on Physical Therapy on relative permeabilities to the ultraviolet radiations.

The relations between the seasonal variations of the solar spectrum and of morbidity and mortality will be reported later.

---

[4] Sample provided by the Manufacturers' Glass Company, Chicago.

Nature of Auricular Fibrillation.—A great deal of experimental work has been done on the results of high-speed direct stimulation of the heart's auricular appendix. It is found that when the stimulation speed rises to from 300 to 500 a minute the ventricular responses are usually grossly irregular in force and rhythm. In some cases cessation of stimulation is not followed by return to normal rhythm, but the events in the heart continue exactly as if electrical stimulation were still going on. . . . The condition is known as circus movement. . . . When, however, the speed of circus movement in the auricular muscle rises to 450 a minute or thereabouts the path of the circuit is constantly changing, as is the path of the offset waves, the progress of both being constantly impeded by fibers still fatigued, and therefore refractory to stimulation. The result is an irregular circus movement, constantly changing its course, and irregular offset waves which may, or may not, succeed in traversing the whole of the auricular muscle sheet. From this it follows that the arrival of impulses at the auriculoventricular junctional tissue will be both high in speed and irregular in rhythm. The consequent ventricular responses will show a like result, and the ventricular stroke, therefore, becomes grossly irregular and of high speed. This condition constitutes auricular fibrillation.—Langley, G. J.: Nature and Treatment of Auricular Fibrillation, *Brit. M. J.*, June 11, 1927.

A RAPID AND SIMPLE METHOD OF DETERMINING NERVE INJURIES IN THE EXTREMITIES

K. WINFIELD NEY, M.D.
Professor of Neurosurgery, New York Polyclinic Medical School and Hospital
NEW YORK

The late discovery of a nerve injury in a traumatized extremity, particularly when following the débridement of a wound, the adjustment of a dislocation, the setting of a fracture or the application of a splint, is a serious event in the experience of the traumatic surgeon, and certainly the burden of responsibility rests on that surgeon who only after some operative intervention on an extremity discovers the presence of a nerve injury that was not mentioned in the preoperative records. As a rule, the average surgeon feels that the examination of an extremity for a nerve injury is a process requiring considerable technical skill and neurologic knowledge, and that such an examination, to be reliable, should be made by a neurologist. While this is true in some respects, it nevertheless does not excuse the surgeon for overlooking and neglecting a nerve injury. It is commonly believed that to examine an extremity for a nerve injury, splints and dressings must be removed, thereby jeopardizing the position of fractures and risking infection of wounds. It is possible, by simple tests which may be conducted within a few seconds, to determine definitely the presence or absence of injuries to important motor nerves of the extremities when observation permits only inspection of the hand or foot, and no preoperative record of a traumatized extremity is complete without this information.

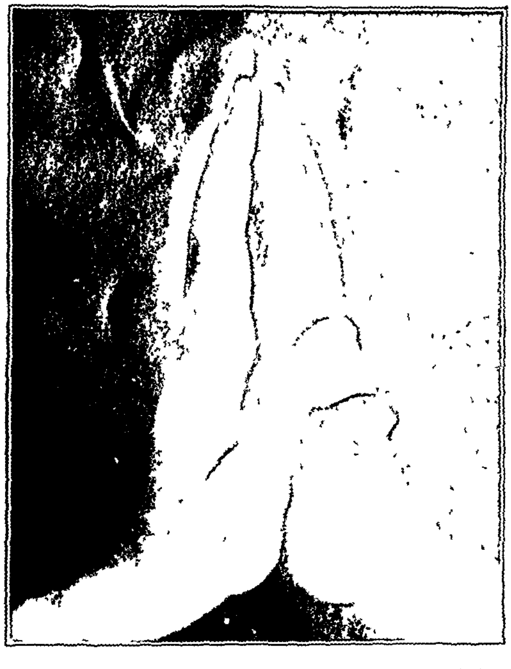

Fig. 1—Musculospiral nerve paralysis normal extension of the thumb of one hand and inability to extend the thumb of the other denoting a *musculospiral paralysis, manifest in the loss of complete thumb extension*

In my observation and treatment of more than 1,500 nerve injuries while in military service, and some 200 occurring in civil life, systematic examination has revealed that these injuries, with very rare exceptions, all involve, to some degree, even in the slightest injuries, the motor function of the fingers and toes, and that, with the exception of the upper arm type of brachial plexus lesions, an inspection of movement in the fingers and toes will reveal nerve involvement. Isolated injuries to the musculocutaneous, circumflex and anterior crural nerves are rare, and, excepting the upper arm type of brachial plexus lesions, injuries to the circumflex and musculocutaneous practically always involve either the median, ulnar or musculospiral. The upper arm type of brachial plexus lesion may be readily determined by paralysis of the deltoid, biceps or triceps—most commonly all three. Injuries to the anterior crural nerve resulting in complete loss of extension of the leg are exceedingly rare, as the nerve on leaving the abdominal cavity has divided into a number of branches, all of which are rarely involved, and in serious injuries the involvement of the adjacent femoral artery completely overshadows the nerve lesion.

An injury to the musculospiral nerve in any part of its course, even to the lowest portion of the posterior interosseus nerve, will result in loss of extension to the thumb. Therefore, inability to extend the thumb completely immediately suggests a musculospiral involvement.

With the median nerve, injury in any location will affect the opponens pollicis, making it impossible to oppose the palmar surface of the thumb to the pads of the extremity of the fingers. While it may be possible to flex the terminal phalanx of the thumb through the long extensor, or the first phalanx by action of the flexor brevis pollicis, which is partially supplied by the ulnar nerve, it is impossible to rotate the thumb over the palm.

Fig. 2.—Median nerve paralysis: five fingered cone of one hand, denoting normal median and ulnar nerve intrinsic hand muscle function; of other hand, a four fingered cone, denoting normal ulnar nerve function and median nerve paralysis, in that the thumb cannot be opposed to the center of cone—it rests on the side of the index finger.

In injuries of the ulnar nerve, the interosseus muscles are conspicuously involved, which prevents lateral movement of the fingers. Examination of the fingers will reveal the absence of these lateral movements by the inability to make the fingers into a cone; that is, bunching the ends of the fingers. Normal ulnar motor action will permit the formation of a four finger cone; normal median nerve action will permit the rotation of the thumb and the placing of its palmar surface against the tips of the ulnar cone, making a five finger cone. A patient able to make a five finger cone with the tips of his fingers does not have motor disturbance involving the median or ulnar nerve. Therefore, the test of making a five finger cone and the extension of the thumb will immediately determine the presence or absence of a musculospiral, median or ulnar nerve injury.

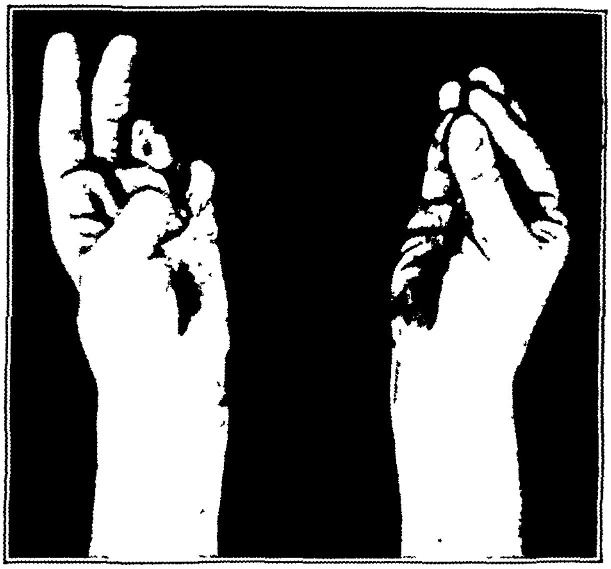

Fig. 3.—Ulnar nerve paralysis: normal five fingered cone of one hand; the other hand, unable to make a four fingered cone, shows ulnar nerve paralysis; apposition of thumb possible, demonstrating a normal median nerve.

Musculospiral injuries may be further confirmed by determining the presence of anesthesia over the dorsal surface of the base of the thumb, and also inability to elevate the wrist and extend the fingers at the metacarpophalangeal joint. If the patient can make a four finger cone, but is unable to oppose his thumb to the finger tips to make a five finger cone, he has a median nerve paralysis, which may be confirmed by determining the loss of sensation in the palmar surface of the first three fingers and by the inability to flex the index finger when the other fingers are extended. A patient who is unable to make a four fingered cone has an ulnar paralysis which may be confirmed by determining the loss of sensation in the little finger, and by testing the action of the interosseus muscles in individual lateral movements of the fingers.

In examination of the lower extremities to determine the presence of an injury to the sciatic trunk or its two terminal divisions, the tibial and peroneal nerve, it is usually sufficient to inspect movement in the toes. If the toes can be extended, one may readily conclude that the peroneal nerve and the peroneal portion of the sciatic (external popliteal) has escaped injury. If the toes can be flexed, the tibial nerve (internal popliteal) and the tibial portion of the sciatic have escaped injury. If the patient is unable to extend the toes, a peroneal injury may be confirmed by the loss of sensation in the cleft between the great and second toe—also by the loss of dorsal flexion in the foot (extension). The inability to flex the toes means an injury to the tibial nerve or the tibial portion of the sciatic, which may be confirmed by loss of sensation in the sole of the foot and the toes, and the inability to plantar flex the foot.

The simple tests of making a five fingered cone and extending the thumb, and of determining upward and downward movement of the toes and foot, will readily assist the surgeon in determining the presence or absence of important nerve injuries in the extremities, with the very rare exceptions mentioned.

In determining the presence of a nerve injury and confirming the observations by sensory tests, the surgeon may save himself considerable future embarrassment, be able to modify his prognosis accordingly, and institute proper treatment and correct splinting to prevent overstretching of paralyzed muscles.

853 Seventh Avenue.

REDUCTION OF CERVICAL DISLOCATION

REPORT OF A SUCCESSFUL CASE

VICTOR F. MARSHALL, M.D.
AND
CLARENCE C. REED, M.D.
APPLETON, WIS.

Cervical dislocations without fatal results are of more frequent occurrence than is generally thought. Because of its supposed rarity cervical dislocation has not received the attention and investigation that its importance deserves. However, the condition has been rather fully discussed by Walton [1] and Scudder,[2] and cases have been reported by Barnett,[3] Erickson,[4] Huff,[5] Langworthy,[6] Speed,[7] Wusthoff [8] and others.

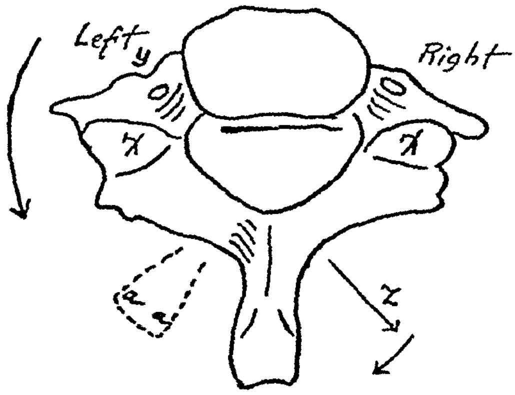

Fig. 1.—Direction of tilting and rotating in reduction (Walton).

These dislocations are produced by carrying the movements of rotation and abduction beyond their normal limits, by any force which overabducts or overrotates the upper part of the spinal column. The force may be an external one or one developed by the muscles attached to the head (Stimson).

The symptoms vary greatly from paralysis or death when there is compression of the cord, as usually occurs in bilateral dislocation, to a posture of the head simulating a torticollis, and they may even go unrecognized.

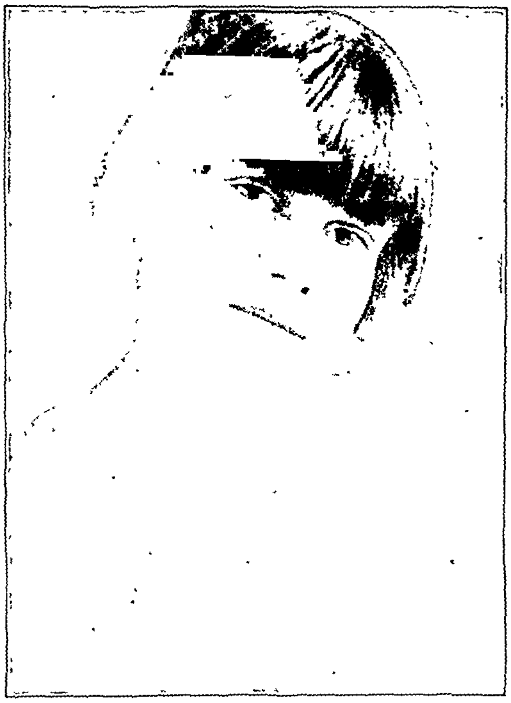

Fig. 2.—Appearance of patient before reduction.

A painful prominence can often be noticed on the dislocated side.

Even when paralysis or special pain is not present, there is usually considerable disfigurement and the relief of the condition is much desired. By the method of Walton, such relief is easily obtained when the relation of the anatomic parts involved is thoroughly understood. However, fracture sometimes occurs and should be considered before reduction is attempted.

In the complete unilateral dislocation, the articular process of one vertebra slips forward and falls down into the intervertebral notch of the vertebra below. This accident can easily happen because of the horizontal position of the articular processes (Spalteholz). The ligaments then hold the vertebra in the new position and the muscles play little part. As a result, the head is tilted to one side and twisted so as to produce a position similar to torticollis. In the new position the head is immobile; the muscles are lax on the side which would have produced the deformity and tense on the opposite side.

The essentials of Walton's plan of reduction, as worked out by him in a series of experiments on the cadaver and used clinically, are: (1) dispensing entirely with extension, and (2) using only retrolateral flexion and rotation.

The proper method is simply to raise the depressed process and rotate. This can be accomplished only by extending the head obliquely backward toward the right or left as the case may be and using the transverse process on the same side as a fulcrum. The ligaments which have held the vertebra firmly in its faulty position do not offer opposition to this movement, so that force is not required first to elevate in this way and then to rotate to the proper position. Walton, quoted by Scudder,[2] demonstrated this method as follows:

> The diagram [fig. 1] shows the upper surface of the lower of the two vertebrae concerned, that is, the one in normal position. The articular processes of this vertebra are marked *x, x*. The *left* articular process of the vertebra above having slipped into the intervertebral notch *y*, the situation of its spinous process will be indicated by the dotted lines *a, a*. The direction in which the head must be tilted for reduction is indicated by the line *z* (in other words, if the patient is facing the north the head must be tilted southeast). Slight rotation in the direction of the short curved arrow on the right of the diagram may be necessary to free the process. After the articular process is freed, rotation into place in the direction of the long curved arrow on the left of the diagram will complete reduction. In case the *right* articular process has been displaced by the dislocation, these movements should be reversed.

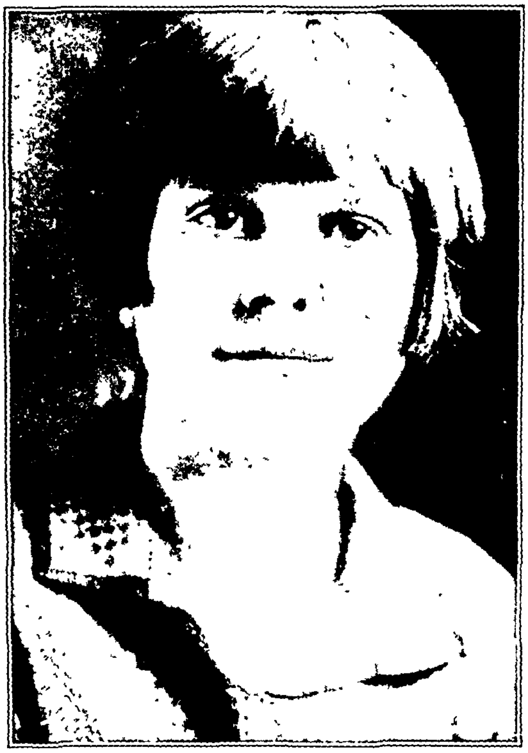

Fig. 3.—Appearance after reduction.

The patient should be thoroughly anesthetized (nitrous oxide), and should be in the sitting position. This gives freedom of movement and prevents confusion of the proper movements of reduction.

REPORT OF CASE

M. H., a girl, aged 12, brought to St. Elizabeth Hospital, Appleton, Wis., Nov. 10, 1926, had been forcibly thrown from an automobile when the auto was hit by an interurban car. She was picked up in an unconscious condition and remained so for eighteen or twenty hours after entrance into the hospital. When she regained consciousness she complained of some headache, stiffness and pain in the neck, and inability to turn her head. Her past and family history were entirely negative.

On examination it was noted that the head was turned to the left; the face was also bent toward the left side, and she held the neck and head in a rigid manner (fig. 2).

There was a tender, palpable, firm mass on the left side of the neck just below the hair line. The patient was unable to turn her head except to a very limited degree and then to the left only, and she complained of pain and discomfort in the neck when an attempt was made to turn her head.

There were minor abrasions and contusions of the face, left eye and left shoulder.

The superficial and deep reflexes were normal and there were no sensory disturbances.

Roentgenograms revealed a displacement forward and to the right of the atlas and axis on the third cervical vertebra, and there was distinct angulation between the third and the second and first cervical vertebrae in the anteroposterior direction. There was only a slight narrowing of the neural canal, but no evidence of fracture. However, there was a fracture without separation of the inner extremity of the right zygomatic arch.

November 20, under nitrous oxide-oxygen anesthesia, the dislocation was reduced by the method of Walton and a light plaster cast applied to the shoulders, neck and head. The patient was put in bed flat on her back but the next morning it was observed that the dislocation had recurred. Two days later it was again reduced, and a snug plaster collar about 3 inches wide was put around the neck and over this a fairly heavy cast which included the shoulders, neck and head was applied. The patient was kept in bed for one week, and then sent home. Four weeks after reduction the cast was removed, and she was able to move the head in all directions. Five months later the patient is well, and there is no deformity (fig. 3) or limitation of motion.

PRELIMINARY DIVERTICULOSTOMY IN DIVERTICULUM OF BLADDER

UNUSUAL CASE AND METHOD OF OPERATION

DAVID M. DAVIS, M.D.
ROCHESTER, N. Y.

Diverticulum of the bladder is fascinating from a surgical standpoint, and the problems to which it gives rise are of never ending complexity. The case reported here will illustrate the surprises it may hold in store for the surgeon:

REPORT OF CASE

H. A., aged 73, a widower, seen at the Park Avenue Hospital at the request of Dr. Alvah S. Miller, Oct. 21, 1925, had always been well and strong, not having had illness during his life until about five or six years before, when he noticed slight difficulty in starting the urinary stream and slight frequency of urination. The difficulty increased. The frequency never became very pronounced. During this period the general health became impaired; the bowels became very constipated and the mind less clear.

Five weeks before, while away on a vacation, the patient was found lying on the floor in convulsions and foaming at the mouth. After being in bed for some days, while still unconscious, he was brought back to Rochester. At that time the blood nonprotein nitrogen was very high—in the neighborhood of 200. The treatment was by rest in bed, bland diet, and forcing of fluids. The patient gradually improved for a period of a month, at which time he was out of bed part of the time and the mind comparatively clear. At this point, however, improvement ceased. When first seen the patient was voiding four or five times during the day and six or seven times at night. Urination was difficult and painful. The blood nonprotein nitrogen was 32; creatinine, 1.5. The urine contained pus and in the preceding two days there had been slight fever, rising to 101 F. There had never been any urethral instrumentation. The patient suffered from insomnia and mental depression and was very constipated.

Examination showed the patient to be well nourished, with skin and mucous membranes of good color. The tongue and lips were dry. The pulse was regular, and of good force and rhythm. No mass or tenderness existed in either kidney region. The abdomen was normal except for an area of flatness extending four finger-breadths above the symphysis and within an inch of the umbilicus. Pressure over this region was slightly painful. The external genitalia were normal. Rectal examination showed a markedly enlarged prostate, which was smooth, round, elastic and not adherent. The seminal vesicles were slightly corded, but otherwise normal. There was moderate edema of the ankles. Urinary obstruction, due to an enlarged prostate, was present, and in spite of the rather surprising fact that the blood nitrogen had returned to normal while the obstruction was still unrelieved, it was felt that drainage of the distended bladder was necessary. Efforts to introduce a catheter were unsuccessful, all types being arrested in the prostatic urethra.

October 22, under gas and oxygen anesthesia, a median suprapubic incision was made, exposing a markedly distended organ which was thought to be the bladder. Incision allowed a quantity of urine to flow out, and a large mushroom catheter was put in place. It was noted at the time that the wall of the bladder seemed extremely thin. No intravesical palpation was attempted, the patient's condition being considered precarious. The bladder capacity was 750 cc. Following the operation the patient did very well and showed marked improvement. The systolic blood pressure, which before the operation had been 180, fell to 150.

November 9, a cystoscope was inserted through the suprapubic fistula, showing what appeared to be the interior of the bladder. The walls were everywhere smooth and pale, and a good sized calculus was seen. In the right lateral wall of this cavity was a large diverticular orifice. The base of the bladder did not show any of the usual landmarks, and it was impossible to locate ureters, trigon, urethral orifice or prostate. The area where they should have appeared was occupied by a smooth, round convexity. The cystoscope was then passed through the diverticular orifice. More stones were seen within the second cavity, and the mucous membrane lining it was much rougher and more reddened. It was impossible to explore the more distant parts of this cavity. November 19, in order to estimate the size and location of the diverticulum, a cystogram was taken, 250 cc. of 5 per cent sodium iodide being introduced through the drainage tube. A plain roentgenogram had shown several good sized stones lying in the bladder region (fig. 1). The cystogram (fig. 2) showed the drainage tube leading into a large, pear-shaped cavity, with very clear regular outlines, situated in the left half of the pelvis. This communicated, by a narrow passage, with another cavity of about the same size, pushed over into the right half of the pelvis, which by its irregular outlines was identified as a trabeculated bladder. In the lower portion of this shadow was a filling defect, apparently due to a large intravesical prostatic lobe. It now became evident that at the time of operation the large diverticulum had pushed up in front of the bladder and that the drainage tube had been placed in the diverticulum and not in the bladder at all. When the cystoscope had been passed through the diverticular orifice it had gone, not into the diverticulum, as was thought at the time, but into the bladder proper.

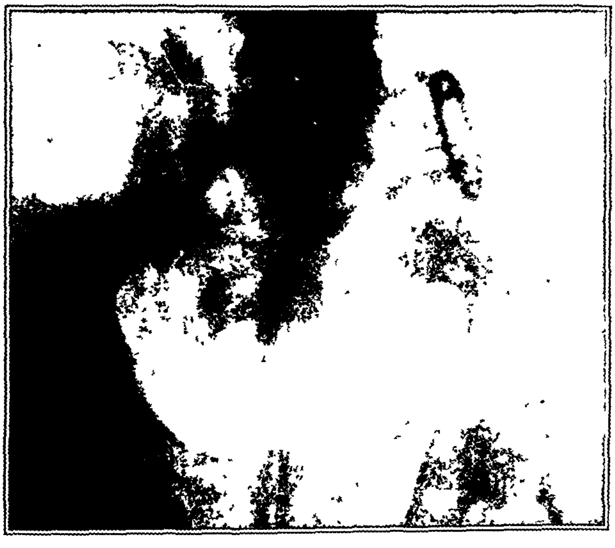

Fig. 1.—Appearance after diverticulostomy, showing drainage tube in diverticulum, deflected to left The three stones to the left are in the diverticulum; the two to the right in the bladder

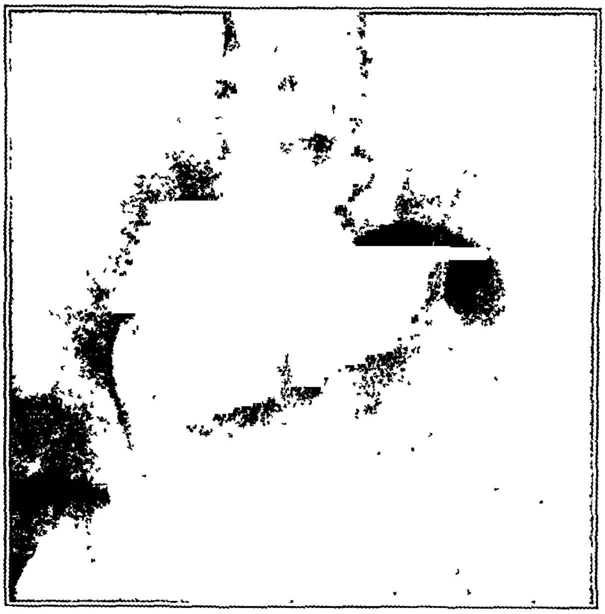

Fig. 2.—Cystogram made by introducing 250 cc of 5 per cent sodium iodide solution through drainage tube The diverticulum has contracted after drainage and now occupies the left side of the pelvis It is pear-shaped and perfectly smooth in outline, and is connected with the bladder by a moderate sized opening The bladder, which is pushed to the right, is markedly trabeculated In its lower portion is a filling defect due to the large intravesical median lobe The outline of the extravesical portion of the prostate is shown below, apparently by a thin layer of calcification about its periphery

December 9, six days after the patient had received a transfusion of 800 cc. of citrated blood, which had a very beneficial effect on his general condition, operation was performed, with the idea of removing the diverticulum and the stones, and then, if the patient's condition permitted, of enucleating the prostate.

Under ethylene anesthesia, a median suprapubic incision was made, encircling the fistula. The fistula was then dilated sufficiently to admit Young's prostatic tractor, which was opened out within the diverticulum. Pulling the diverticulum upward with this instrument, the dissection was rapidly and easily carried downward on each side of, and below, the fistula, freeing the diverticulum laterally and from the posterior surface of the symphysis. Attention was then turned to the upper aspect of the fistula, where, by dissecting on the tractor within the diverticulum, it was easily possible to separate the reflection of the peritoneum, which came very close to the fistula (fig. 3). As soon as the reflection was found, a good line of cleavage appeared which enabled the peritoneum to be pushed back without injury. Still pulling the diverticulum upward with the tractor, one found the remainder of the process of freeing it down to its attachment with the bladder very easy and rapid. When this point was reached it was split, the edges were seized with clamps, and it was then cut off flush with the bladder. With it were removed three large calculi. The opening into the bladder was then enlarged downward, and two more large calculi were removed from the bladder proper Palpation showed a single, large, intravesical median lobe without any intravesical lateral enlargement. At this time the patient's pulse was 84 and of good quality, and the general condition excellent. It was therefore determined to proceed with the removal of the prostate, which was done in the usual manner, the median lobe and two extravesical lateral lobes being enucleated. A Hagner bag was drawn into the prostatic cavity, arresting all hemorrhage, and the bladder incision was then closed about a large fenestrated drainage tube. A good sized rubber drain and a small gauze pack were then placed in the cavity left by the removal of the diverticulum, and the abdominal wall was closed in the usual manner. At the end of the operation the patient was slightly pale, but the pulse was only 90; 2,000 cc. of salt solution was given subcutaneously.

The suprapubic fistula closed, Jan. 16, 1926, thirty-eight days after the operation. The urethra and vesical orifice were dilated on three occasions with the Kollmann dilator. The patient left the hospital, February 1, fifty-three days after the operation. At this time he was walking about, voiding freely and painlessly, and with perfect control, although there was still some frequency. The urine showed a small quantity of pus but was otherwise normal. Examination of the removed prostate showed that it consisted entirely of benign epithelial hypertrophy except for one tiny area corresponding to Albarran's "epitheliome adenoide."

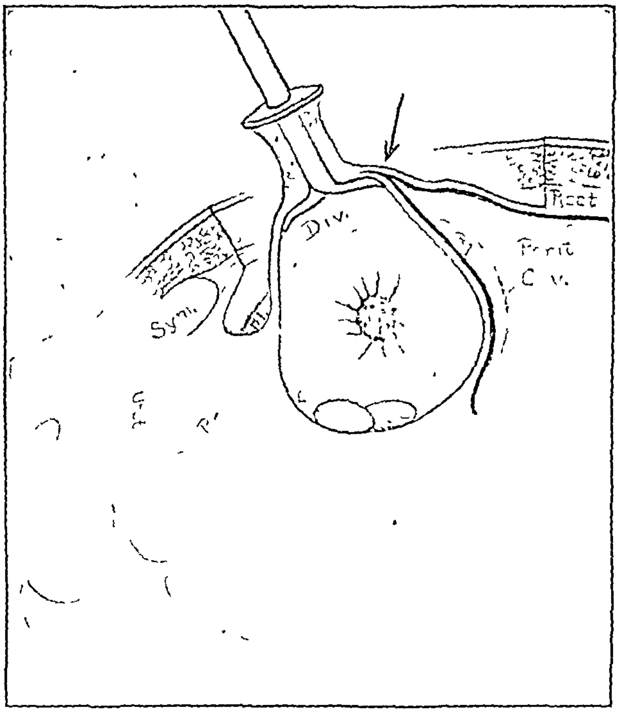

Fig 3.—Diagrammatic sketch showing diverticulum pulled up by Young's prostatic tractor, passed through the fistula Arrow indicates point at which dissection of peritoneal reflection from diverticulum was begun. *Sym*, symphysis pubis; *Uret.*, urethra; *Pr.*, prostate; *M. L.*, median lobe; *Bl*, bladder, *Div*, diverticulum; *Rect*, rectus abdominalis; *Perit Cav*, peritoneal cavity.

The patient was perfectly comfortable and had no further urinary difficulty while at home. About June 1, six months after the operation, he suffered two cerebral attacks, the first of which caused left hemiplegia, while the second proved fatal.

COMMENT

The size and location of the diverticulum in this case were very unusual. It had evidently originated from a point considerably higher on the left lateral wall of the bladder than is the usual site of diverticulum formation, so much so that as it enlarged it pushed forward into the prevesical space rather than backward or upward, and at the time of the cystostomy it had passed well beyond the median line. The misconception to which this gave rise was not cleared up until the cystogram was taken. This misconception, however, was without evil consequences since drainage of the diverticulum instead of the bladder had no disadvantages, but indeed was advantageous, since the urine, entering the bladder from the ureters and leaving the diverticulum through the drainage tube, passed through both bladder and diverticulum, and there were therefore no undrained areas in which infection could develop, as does occur when the drainage tube is placed in the bladder instead of in the diverticulum.

The presence of the fistula leading into the diverticulum provided a further advantage at the time of operation, since it enabled an instrument to be placed at once in the diverticulum, with which it was drawn up and its dissection tremendously facilitated.

The method by which a diverticulum should be removed depends entirely on its size and relationships to other organs. There is no doubt that diverticula developing posteriorly and lying for the most part behind the bladder are best removed by an intravesical operation, in which the diverticulum is preferably drawn up into the bladder and amputated. When the diverticulum lies laterally, or, as in this case, anteriorly, or when it is at the vertex of the bladder, the extravesical method is preferable in many cases. The experience in this case shows clearly, I believe, that when the cystogram indicates that the diverticulum reaches the midline, or even approaches within reasonable distance of it, it is well to perform diverticulostomy rather than cystostomy, whenever preliminary bladder drainage is indicated. The advantages of this procedure are particularly apparent in cases in which the diverticulum is heavily infected. By causing a continuous flow of urine through the diverticulum, stagnation is avoided and infection more easily reduced. When the time arrives for diverticulectomy, the fistula provides an easy path to the diverticulum and a means of producing traction on it without delay. This is particularly desirable when the diverticulum lies in close contact with the peritoneum.

The further lesson to be drawn from this case is the always valuable one that surprising results can be accomplished in cases, apparently the most unfavorable, by careful and cautious work, care always being taken that the patient is equal to the procedure contemplated. Preliminary drainage by cystostomy or retained catheter, copious administration of fluids, transfusion and digitalis will work wonders in restoring the patient suffering from urinary retention and enable him eventually to withstand, without difficulty, operative procedures which would surely be fatal if attempted too soon, but which, when properly carried out, will restore him to health.

Roentgen Ray in Diagnosis of Pulmonary Disease.—The appearance of the youngest tubercle is unknown, though some believe it represented by the minute, ill defined shadows designated "budding twig," "pussy-willow," "cottony" or "snowflake" irregularities seen along the radiations of the bronchovascular tree in the subapical and apical regions of the lungs. Probably the premise is more sound than when the film shows in the upper third of the chest what is termed a "cirrhus cloud," or "soft spotty mottling," or infiltration, the conglomerate tubercle is visualized. Such shadows are denser at the center and fade out toward the periphery to margins that are more or less hazily defined. When coalescence of such areas occurs, light areas may be seen in the zone of confluent density, indicating that consolidation is not complete. Necrosis or caseation is indicated by the appearance of areas of paling or of clearing. . . . The evolution of such changes can be studied with the aid of a series of roentgenograms.—Austrian, C. R.; *Am. J. M. Sc.*, June, 1927.

FURTHER EXPERIMENTAL STUDIES IN CHOLECYSTOGRAPHY

PATHOLOGIC OBSERVATIONS *

JULIUS FRIEDENWALD, M.D.
MAURICE FELDMAN, M.D.
AND
FRANCIS X. KEARNEY, M.D.
BALTIMORE

Since the introduction of tetraiodophenolphthalein into medicine for purposes of visualizing the gallbladder, attention has frequently been directed by various observers to the toxicity and the hepatic and renal lesions produced by this dye. Graham and Cole[1] were able to note toxic effects only when large doses were administered intravenously. However, Ottenberg and Abramson[2] have reported the production of extensive degeneration amounting almost to necrosis of the liver lobules following the injection of a 5 per cent solution of the dye in doses of from 0.3 to 0.4 Gm. per kilogram of body weight. Lesions were found in addition in the kidneys and spleen. The urine showed large amounts of the injected dye, albumin, casts, and in some instances hemoglobin. Larger doses killed the animals at once or within fifteen minutes with acute convulsive seizures. They note, however, that the doses required to produce symptoms and lesions in the liver were enormously larger than those employed in the tetrachlorphenolphthalein liver function test. They further state that "the amount of tetrabromphenolphthalein used for gallbladder visualization is also safely below the toxic doses; the margin, however, is not so large and suggests the necessity of caution in cases in which the liver parenchyma is already damaged by disease."

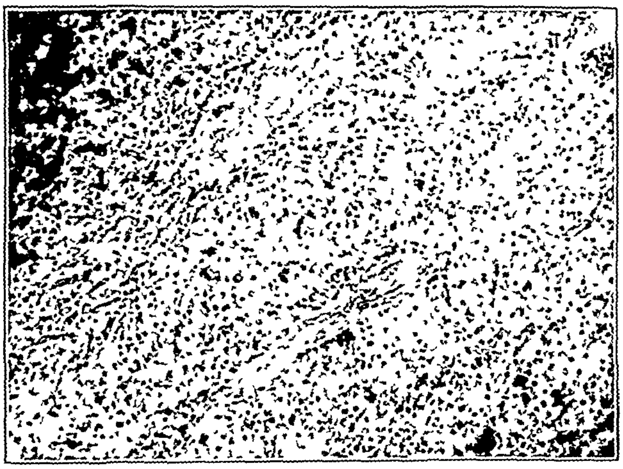

Fig. 1.—Section of kidney (low power): moderate cloudy swelling with slight arterial injection.

Rosenau[3] also cautions against the indiscriminate administration of the dye, and points to clinical and experimental work as indicating the possibility of liver injury following its injection. He concludes that because of the toxicity of the halogenated phthalein compounds they should be employed cautiously and only in moderate doses.

As the oral method of gallbladder visualization is nowadays practiced to a large extent, thus replacing the intravenous method, the question presents itself as to whether a similar toxic effect or liver injury might arise as the result of this method of administration. This appears the more important to us, since in the experimental work that has been reported up to the present, the dye has been administered intravenously.

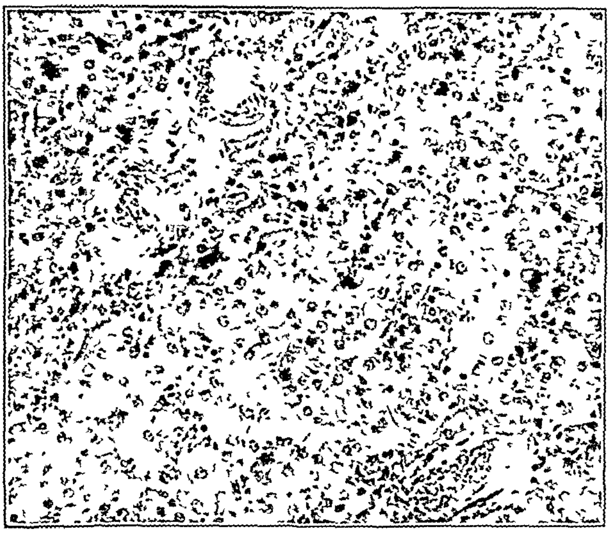

Fig. 2.—Section of kidney (high power).

It is of interest to note that Abel and Rowntree[4] in their original experiments, as far back as 1909, report that when phenolphthalein or its tetrachlor derivatives were administered to animals, ill health did not result. *In numerous autopsies lesions could not be detected* that could be referred to these compounds, and the liver showed no abnormality.

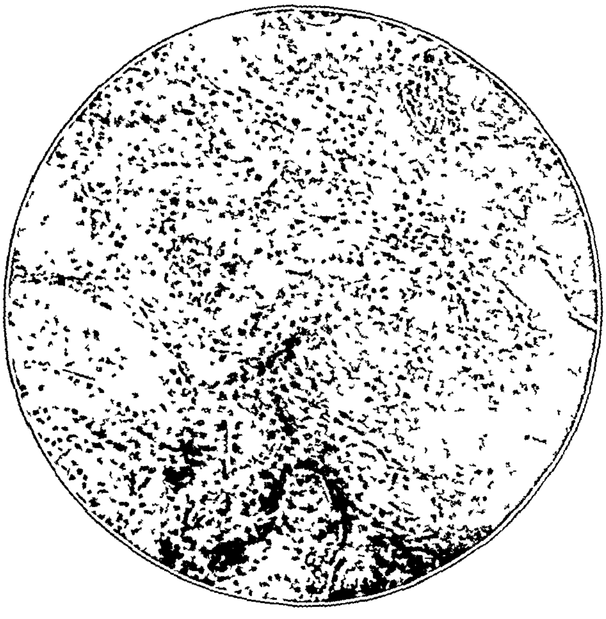

Fig. 3.—Section of liver (low power): hyperemia, moderate edema and moderate fatty changes.

[4] Abel and Rowntree: J. Pharmacol. & Exper. Therap. 1: 231, 1909.

As there still appears to be some doubt with regard to the degree of toxicity and the lesions that may be produced by this dye when administered by the oral route, it seemed to us that further experimental evidence was needed to solve this problem definitely. This appears the more important, as at times the dosage of tetraiodophenolphthalein required in cholecystography must necessarily be extremely large.

In the course of our recently reported experiments[5] on cholecystography by the oral route, large doses of the dye were administered by mouth and directly into various parts of the small bowel at frequent intervals.

Twenty-one dogs were utilized in these experiments. The quantity of tetraiodophenolphthalein administered to each varied between 3.8 and 31.6 Gm., given in divided doses within a period of less than two months. Three dogs not given dye were utilized as controls. These animals were finally killed and the liver and kidneys removed for histologic examination. In a single dog, before any dye was given, a small portion of the liver was excised for a similar purpose, and later compared with another portion of the liver of the same dog, removed following the administration of the dye. In no instance could the death of any of the dogs be attributed to the toxic effect of the dye. The cause of death was due, either to the shock of the operation, excess of ether, or, finally, to starvation.

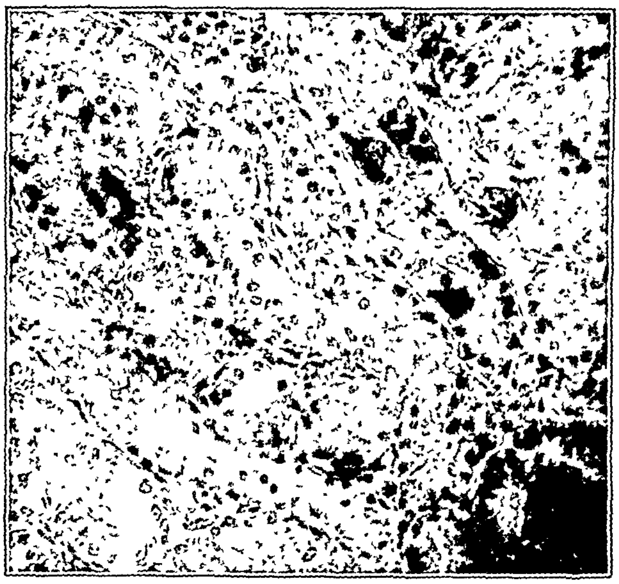

Fig. 4.—Section of liver (high power).

The histologic conditions noted in the kidneys and liver were as follows: (1) normal; (2) congestion; (3) cloudy swelling; (4) early fatty changes; (5) small round cell infiltration about the bile ducts, and (6) moderate fibrosis about the bile ducts. Similar changes were noted in our normal and control dogs, as well as in the dog whose liver was examined before as well as after the administration of the dye. Regardless of the quantity of dye given, all the dogs showed some of the histologic changes just noted. These changes are frequently postmortem conditions, and are observed in dogs dying from starvation or as a result of the ether. In no instance was there evidence of degeneration or of necrosis as has been reported by other observers.

In five instances in which catheterized specimens of urine were examined following the administration of large doses of the dye, no abnormal conditions were revealed. This is entirely in accord with our observations in human beings following the use of the dye for gallbladder visualization.

It is interesting to note that, contrary to the observations of Abel and Rowntree, the dye is absorbed not only in the large bowel but also in the small intestine. By tying off the first portion of the duodenum and also the terminal ileum and injecting a large quantity of the dye into the second portion of the duodenum, we were able to visualize the gallbladder satisfactorily in three dogs. This indicates that absorption takes place not only in the large but also in the small intestine.

As an explanation of the failure of others to obtain absorption of the dye in the small intestine, our former experiments reveal that the gastric acidity is so high in dogs as to acidify the contents of the small bowel to such a degree as to prevent absorption. This is due to the transformation of the dye into an insoluble salt.

CONCLUSIONS

From these experiments it is evident that when tetraiodophenolphthalein is administered orally for purposes of cholecystography, even when given in massive doses, it does not produce degenerative or necrotic changes in the liver or kidneys.

Clinical Notes, Suggestions and New Instruments

GUNSHOT WOUND OF THE BLADDER

Montague L. Boyd, M.D., Atlanta, Ga.

It seems extraordinary that a bullet could pass through a man's pelvis and not injure any important structure except the bladder. It is also astonishing that in spite of the fact that the bullet passed through the bladder no blood was found in the urine until forty-eight hours after the injury.

Early Thanksgiving morning of last year a healthy, large man, aged 42, while hunting, was accidently shot in the left buttock with a 22 rifle. Immediately an aching pain began in the rectum, and he had some pain in the right hip and thigh, which was worse on walking.

Though the discomfort in the rectum and the aching pain in the right thigh continued, and he had to have morphine for relief, he had no other symptoms of trouble except fever. The afternoon of the day of the injury his temperature rose to 101.2 F ; the next day it was 99 in the morning and 100.1 in the evening.

A microscopic examination of a catheterized specimen of urine made a few hours after the injury did not show blood, nor was any blood seen in the urine until forty-eight hours after the injury, when the patient passed urine well colored with blood; the evening before he had been given a soapsuds enema, which he could not expel and which was later siphoned off.

Blood was not obtained from the rectum at any time, and a proctoscopic examination by Dr. Troy Bivings (with whom I saw the patient) the day of the injury did not show rectal injury.

I was not called to see the patient until the evening of the *third day.* Rectal examination at that time showed a soft mass above the prostate which protruded so much that it caused the rectum to fold back over the upper part of the gland. Pressure on the mass caused a distinct discomfort. There was no suprapubic tenderness. The urine was rather bloody, and contained some streptococci and staphylococci (stain).

---

[5] Friedenwald, Julius; Feldman, Maurice; and Kearney, F. X.: Radiology, to be published

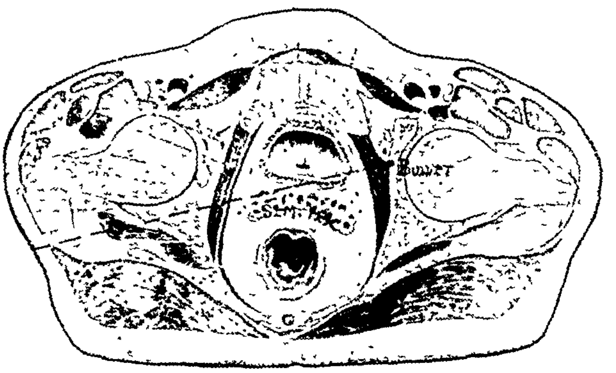
At cystoscopy the mucosa of the distal part of the prostatic urethra, the vesical orifice and the trigon showed a marked edema. The vesical orifice was so much elevated that it was difficult to get the lens of the cystoscope far enough away from the trigon to view it satisfactorily. Beyond this swelling, which extended to the interureteral ridge above and to the lateral walls of the bladder on each side, the bladder seemed fairly normal. In the outer upper edge of the swelling on either side there was a bleeding point, from which so much blood came that I was never able to get a sufficiently satisfactory view to determine the exact location of the bleeding or the extent of injury to the bladder.

On the morning of the next, the fourth, day I made a suprapubic incision and found the perivesical tissues distinctly, though slightly, edematous, and of a slightly unpleasant odor.

With the bladder opened, the area of edema and hemorrhage could be palpated quite easily. It was limited to a fairly sharply defined area back of the bladder, about 6 cm. in diameter and about 4 cm. thick; it was soft, and slightly crepitant. A Pezzar catheter was fastened in the upper, anterior part of the bladder, and rubber drainage tubes were left on each side of the bladder extending down to the area of injury.

A culture made from the fluid in the tissues about the bladder showed a gram-positive coccus "morphologically consistent with staphylococci."

The patient made an uneventful recovery.



Schematic representation of the course of the bullet The actual course was probably at a slightly lower level. The bladder was probably full and therefore rounded, so that the bullet passed through only the most dorsal portion. Both seminal vesicles were probably injured, as would have been possible with the bladder full and pushed back between the seminal vesicles. (Photo of a plate in "A Cross Section Anatomy," by Eycleshmer & Schoemaker, published by D. Appleton & Co.)

About two months after the accident he came in, at my request, for an examination. He had had no symptoms from the injury except an aching pain in the right hip when he walked more than usual, and some blood in the semen on several occasions. Urination was not disturbed.

The urine was clear, and a rectal examination showed a raised fold of tissue running across the pelvis at the level of the upper part of the seminal vesicles which was evidently scar tissue along the tract of the bullet. The prostate seemed normal. The seminal vesicles could not be palpated.

COMMENT

It is difficult to explain why there was no blood in the urine for from twenty-four to forty-eight hours after the injury, but it is interesting and important to observe that the bladder can actually be penetrated by a small caliber bullet without showing even microscopic evidence of blood.

There is no doubt in my mind about the bladder having been penetrated. The bleeding was profuse at cystoscopy, and there was no question that there had been an extravasation of urine into the tissues about the bladder.

The surgeon with whom I saw this patient made me feel that he needed to be convinced that the suprapubic exploration which I advised was necessary. Such a necessity in cases of this kind is difficult to demonstrate, but in my experience it is far safer to make a suprapubic incision and explore the bladder region for extravasation than it is to run the risk of permitting an extravasation to go undrained.

RAPID FILTERING APPARATUS STOPPED AUTOMATICALLY AND AT WILL

Moses Einhorn, M.D., New York

In order to emphasize the improvements which I claim for the apparatus I am about to describe, a brief summary of the difficulties encountered in the more common methods of filtration is quite necessary. The old method of procedure involved the use of a funnel, beaker and cotton or filter paper arranged in a fashion similar to that illustrated in figure 1. There were many difficulties and disadvantages connected with this old method. In the first place, the filter paper had to be folded into a shape to fit the funnel. Then, too, the rate of filtration was very slow. Constant attention was required to prevent an overflow of the filtrate into the container. Removal of the filtrate necessitated the removal of the beaker containing it and the substitution of another. Filtration could be stopped only by the removal of the filtering material from the funnel.

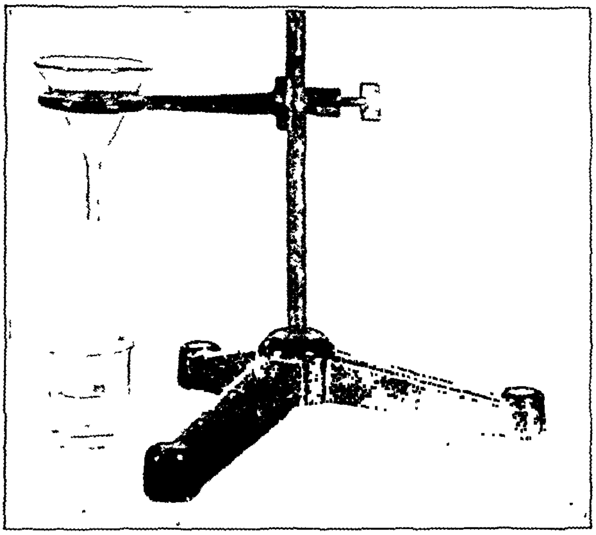

Fig. 1.—Method of filtering ordinarily employed

These difficulties were constantly encountered by me while doing gastric analysis, as no doubt they are in the work of all others who find it necessary to do filtration. After much experimentation and development, I have devised an apparatus which I believe will solve many of the difficulties now encountered while doing filtration, and in presenting it to the medical profession I trust that it will simplify the work of others in this respect as it has mine.

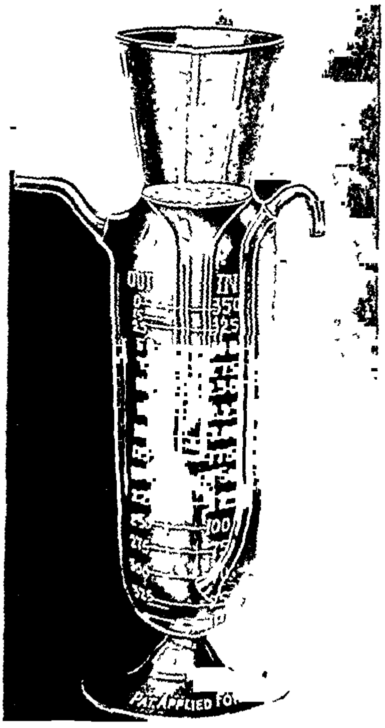

Fig. 2—Rapid filtering apparatus as described by author.

The apparatus which I have constructed (fig. 2) consists of a glass receptacle into which a specially prepared filter-paper cup may be inserted. The bottom of this receptacle is a perforated disk to which is attached a funnel tube which leads into the container and ends some distance from the bottom of it. At the top of the container on the left is a tubelike opening for the escape of air and for the attachment of a suction pump if one is desired. Opposite this opening and in the container (to the right) is a siphon, one end of which terminates just above the bottom of the container, the other in a tubelike opening to which may be attached a rubber tube and stopcock to complete the siphon. Standard measurements (graduated in cubic centimeters) are found on the container. Those on the right, with the arrow pointing up, indicate the amount of filtrate in the container. Those on the left, with the arrow pointing down, are used to measure the amount of filtrate that is removed. The apparatus is made of glass, the parts being closely attached and inseparable, so as to make the device absolutely air-tight. The capacity of the upper cup is always less than that of the space formed by the sides of the funnel and the wall of the container. A cup of filter paper is specially prepared for this apparatus and exactly fits the upper receptacle, thereby eliminating all folding and shaping of filter paper to fit the vessel containing the liquid to be filtered.

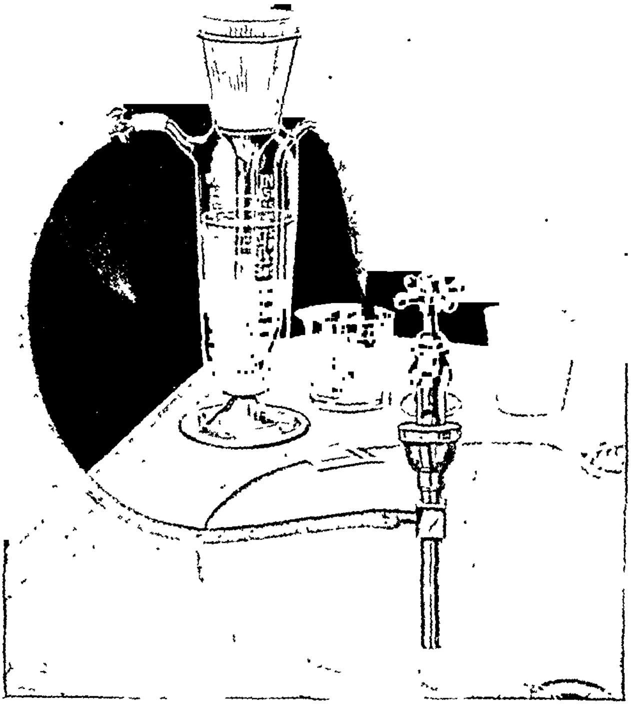

Fig. 3.—Use of suction with author's apparatus.

The use of this new type of filtering apparatus does not radically alter the method employed in the process of filtration. However, in order to obtain the best results, it is necessary to observe the following directions: The filter cup is placed in the receptacle provided for it and the liquid that is to be filtered is poured in. The filtrate then passes through the perforated disk into the funnel tube and through it into the container. When some of the filtrate has already passed into the container, the siphon is filled and the stopcock closed. Filtration proceeds quite rapidly without the use of suction. If more rapid filtration is desired, suction may be introduced in the manner illustrated in figure 3. Through the insertion of a stopcock in the rubber tube attached to the opening at the left, it is possible to control the amount of suction and hence the rate of filtration. The filtrate will rise in the container and after filling the lower part of the funnel tube it will rise in the space between the funnel tube and the wall of the container. When the filtrate begins to reach the level of the higher readings, the suction must be eliminated. The filtration will then continue at a slower rate and will stop automatically when the hydrostatic pressure produced by the filtrate that enters the space plus the atmospheric pressure entering through the opening at the left is equal to the hydrostatic pressure of the filtering material in the cup plus the atmospheric pressure on it. In this fashion, then, the air space in the upper part of the funnel is subjected to equal pressure from opposite forces. The filtration may be stopped at will by shutting the stopcock of the suction tube. The filtrate can be removed by opening the stopcock of the siphon, thus permitting the withdrawal of the filtrate without disturbing the process.

The advantages of this apparatus are obvious and need only a brief description.

1. The provision of a ready-made and shaped filter cup eliminates the necessity of folding and shaping the filter paper as was previously done.
2. The introduction of suction permits rapid filtration.
3. The filtration is stopped automatically.
4. The presence of the siphon makes it possible to remove the filtrate without disturbing or stopping the process.
5. The graduations on the wall of the container permit one to measure, in easy and convenient fashion, both the amount filtered and the amount withdrawn.
6. The filtration can be stopped at will merely by closing both stopcocks.
7. The arrangement permits of continuous filtration and withdrawal of filtrate without in any way halting or stopping the process of filtration.

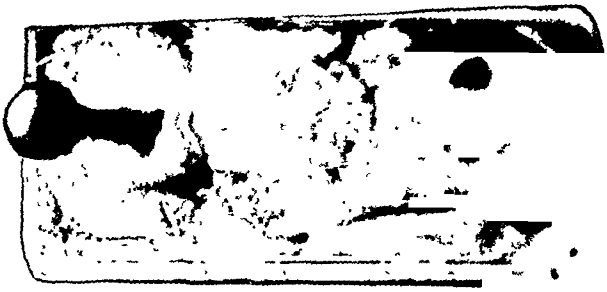
RUPTURED GASTRIC ULCER IN INFANCY: REPORT OF CASE

H. E. Butka, M.D., Los Angeles

Although the literature abounds in reports of duodenal ulcers, the occurrence of gastric ulcer in infants is exceedingly rare. A careful search has revealed only three cases of ruptured gastric ulcer in infants under 2 months of age. In 7,219 autopsies reported by Sturtevant and Shapiro[1] from Bellevue Hospital, there were five cases of gastric ulcer in children. Adler[2] reports twenty-six fatal cases of gastric ulcer in children, nine of which had perforated. Proctor,[3] reporting from the Mayo Clinic for the years 1906-1924, describes only two cases of typical gastric ulcer in children.



Ruptured ulcer with surrounding area of discoloration.

Thiele[4] states that gastric ulcer in children under 16 years of age is comparaively rare, and reports 119 cases. Cackovic[5] found that 2.3 per cent of gastric ulcer in his clinic was in children under 10 years of age. Carteaux[6] reports the first recorded fatal case of ulcer of the stomach in a new-born infant, in 1858. Holt[7] states that gastric ulcer is of great rarity and reports two cases of rupture in infants—one by Rotch at 6 weeks and the other by Cade at 2 months of age.

The symptomatology is variable. Apparently the only characteristic symptom is hemorrhage, occurring as hematemesis or melena with tarry stools. Vomiting is not constant. With perforation there is collapse, high temperature, tympanites and rapid death. Peritonitis develops but is masked by the other conditions. Death usually occurs within thirty-six hours.

The present report is of an infant born in the White Memorial Hospital under the service of Dr. J. P. Mortenson.

REPORT OF CASE

A baby girl, weighing 8 pounds 8½ ounces (3.8 Kg.), was born to Mrs. M. H., a primipara, Nov. 2, 1926, at 11:55 p. m. Labor was induced by castor oil, quinine and enemas, and lasted seven hours. Head molding was slight. Asphyxia was severe, and artificial respiration and oxygen were given. Much mucus was aspirated with a catheter from the pharynx. The baby later became quite blue at times, especially following the administration of fluid. There was much difficulty in swallowing fluids and in nursing. The temperature increased on the third day to 102.6 F. Then she appeared to be somewhat better and rested quietly. Some dehydration was observed, and she raised some thick, tenacious mucus. On the fourth day the mucus was blood tinged and bright blood was vomited. The stools became tarry. All fluids taken by mouth were returned. On the fifth day the child became weaker and cyanotic. In the evening, abdominal distention appeared and became progressively worse during the next twelve hours. Marked tympany was present. Death occurred at 9:15 p.m. of the sixth day.

Autopsy, performed thirty minutes after the death of the infant, revealed that a portion of the cord was still attached but dried up, and the site was well healed. A few small hemorrhagic spots were seen on the nose. A small needle puncture wound was found on the abdomen about 2 cm. below the umbilicus. The abdomen was markedly distended to capacity. Some lividity was present on the back below the shoulders.

When the peritoneum was opened, a large amount of air escaped, with the entire disappearance of distention, leaving the abdominal organs small and collapsed. There was about 500 cc. of air free in the abdominal cavity. The cavity contained some dark clotted blood and fibrin, with some fibrinous material resembling a low grade exudate present over many of the coils of the intestines and especially prominent in both flanks. Much blood clot was found in the stomach, and duodenum, and liquid dark colored fluid blood was present in the jejunum and ileum. The fecal material in the colon was of a lighter color.

Further examination of the stomach revealed externally an area of discoloration and fibrinous exudate over a zone about 2 cm. in diameter, on the greater curvature, about 1.5 cm. below the cardia, and coming into contact with the spleen. Internally, there was found a round crater-like ulcer measuring 8 mm. in diameter and evidently opening into the peritoneal cavity, although the fibrinous exudate had covered most of the opening. Other areas of necrosis of the mucosa were present, but the process had not extended elsewhere to actual ulceration.

The other abdominal organs did not show definite pathologic changes.

Examination of the thorax revealed both lungs partly aerated and partly atelectatic, this being most marked on the left side, involving a portion of the upper and a larger portion of the lower lobe. Patches were also present in the right lung.

The heart was fairly large, and quite normal in appearance. The foramen ovale was patent but fairly well covered by the valvelike membrane.

The anatomic conditions were: perforated gastric ulcer; acute peritonitis; gastric hemorrhage; pneumoperitoneum, and atelectasis.

The probable cause of death was perforated gastric ulcer with hemorrhage and peritonitis.

COMMENT

The interesting features of this case are the age of onset; the occurrence of hemorrhage in the vomitus and stools, and the rapid development of acute distention twenty-four hours before death, presumably corresponding to the time of rupture of the ulcer. This distention was entirely due to free gas in the peritoneal cavity, the intestines and stomach being completely collapsed. The ulcer occurred on the greater curvature in a position readily accessible. Prognosis in peptic ulcer is always grave because of the small amount of blood an infant can lose and still survive. An early diagnosis in gastric and duodenal ulcers in infants is essential.

A UNIVERSAL INDICATOR FOR HYDROGEN ION CONCENTRATION *

EMIL BOGEN, M.D., CINCINNATI

A single solution that will give a continuous change of color with changes in hydrogen ion concentration over nearly the entire range, from strongly acid to strongly alkaline solutions, may serve a multitude of purposes in the clinical and scientific laboratory. Such a mixture, suggested by Moirs of South Africa in 1917, is marketed by the British Drug House. Great accuracy must not be expected from such an indicator, although differences of p_H as low as 0.2 may be distinguished; but for rough approximations or as preliminaries to more exact determinations, it may be found of great value.

The following mixture has also been developed for this purpose, as it has a range from p_H 1.0 to p_H 10.0, with a continuous change of color with change in hydrogen ion concentration: phenolphthalein, 100 mg.; methyl red, 200 mg.; dimethylaminoazobenzene, 300 mg.; bromthymol blue, 400 mg.; thymol blue, 500 mg. Dissolve in 500 cc. of absolute alcohol. Add tenth normal sodium hydroxide solution until the red disappears and the solution becomes yellow (p_H 6.0).

For determining the hydrogen ion concentration of any solution, add one drop of this indicator to 1 cc. of the specimen. The colors produced resemble those of the spectrum, thus:

Red	indicates about p_H 2.0	(very strongly acid).
Orange	indicates about p_H 4.0	(strongly acid).
Yellow	indicates about p_H 6.0	(weakly acid).
Green	indicates about p_H 8.0	(weakly alkaline).
Blue	indicates about p_H 10.0	(strongly alkaline).

For closer approximation, a series of standard solutions for comparison can be made with known buffer mixtures as described by Clark and Lubs.

Indicator papers, made from the indicator solution by soaking heavy filter paper with the alcoholic solution and drying, is very useful, as it may be substituted for litmus paper or similar indicator papers in general use with a consequent amplification of information so obtained. A standard chart may be made in permanent colors to match.

FRACTURE OF OS TRIGONUM: REPORT OF TWO CASES

ROLAND MEISENBACH, M.D., BUFFALO

In reporting these two cases, it may be well to understand that an os trigonum occurs more frequently than is recognized and that its fracture is not unusual. Cases that have shown the presence of an os trigonum are usually those in which foot symptoms other than static errors are pronounced.

I have seen an os trigonum mistaken for an exostosis, spur, hypertrophic exuberance or other condition and, in many cases, entirely overlooked. In a careful diagnosis of foot conditions, an os trigonum, when present, may play a more important rôle than is generally supposed. The two cases reported here clearly illustrate the points in question. These two cases have occurred in a relatively short interval among a large number of foot cases presenting definite symptoms. In these cases, the os trigonum frequently appeared in various forms, but it was fractured only in the ones reported.

REPORT OF CASES

CASE 1.—A man, aged 25, weighing about 160 pounds (72 Kg.), healthy, while playing squash at the university club.

---

[7] Holt, L. E.: Diseases of Childhood and Infancy, New York, D. Appleton & Co., 1916, p. 342.

* From the Department of Biochemistry, University of Cincinnati College of Medicine.

caught his ankle at the side of the court and fell. Examination showed a painful ankle, no swelling of the forefoot, but a definite circumscribed ecchymosis about the size of a penny on the internal and external aspect, just forward of the Achilles tendon at its insertion. Motion at the ankle was not limited and the peroneus muscles were not in a state of spasm. A lateral roentgenogram showed a large os trigonum fractured but not displaced. Convalescence was uneventful; the patient was able to use the foot in two weeks.

Case 2.—A fleshy woman, aged 48, weighing 222 pounds (100 Kg.) with lipomatous nodules in her arms and limbs, stumbled with her foot in dorsiextension and fell. Examination showed a painful ankle with pains referred to the toes, and swelling of the entire foot and ankle. An anteroposterior roentgenogram showed an irregular crack extending entirely through the upper part of the astragalus, but no displacement. The lateral roentgenogram showed a large os trigonum which had been fractured at its base and pushed backward. The ankle surface did not show ecchymosis. Under nitrous oxide and oxygen, the foot was gently manipulated and placed in a firm dressing, and later on a flanged plate. The result was good.

THE PSYCHOLOGIST LOOKS AT THE DOCTOR *

JOSEPH JASTROW, Ph.D.
Professor of Psychology, University of Wisconsin
MADISON, WIS.

I am aware to the point of embarrassment that a psychologist may look at a doctor only from that lowly position of privilege and reverence from which a cat may look at a king; nor have I any designs, feline or otherwise, to psychoanalyze the doctor and disclose any unpresentable repressions or complexes detrimental to the prestige that is the most valuable instrument in his formidable black-bag. As a prescription that I shall presently consider concerns the dissipation of fear, I offer this dose of assurance, in place of any more acceptable consolation suppressed by the freudian censor under the name of Volstead. Nor have I any thesis of startling novelty which might lead you to suspect it as a radical innovation. What I have to say is in the air, or, as we now say, *on* the air, and might be broadcast from any medical station in tune with the modern wave-length.

It takes its start with the truism that a doctor treats patients as well as diseases—a patient with a disorder, the two intricately and at times hopelessly entangled. The physician must forget what the medical student must remember in his dissecting-room period, that the human subject, like Gaul, is divided into parts to be distinguished minutely without confusion. Any such sectional attitude in his vivisectional practice with sensitive human subjects will be as unfortunate as any other false diagnosis.

The doctor is in charge of the health attitude of the personality, which is bound up intimately with the deepest, most vital interests of living. He should not be summoned, like the lawyer, only when his clients are in trouble, though he is there for emergency purposes as well. There is much to be said for the practice of stopping the doctor's pay when the patient gets sick, except that a liking for such immunity from charges might encourage malingering or invalidism. Avoiding the doctor's bills is a stimulus to health that should be recognized in the principles of mental hygiene. The pocketbook nerve, one of the most sensitive in the human organism, is apparently a branch of the solar plexus. The prescription for the doctor, that he should not be so amiable as to encourage recklessly visits from his patients, is easily observed by many doctors that I have met, without violence to their nature. Yet he should not be so objective as to keep his patients at a distance either spacially or socially. Medical diplomacy is a worthy art. Fortunate the doctor who can make friends of his patients, fortunate the patients; though friendliness is not a complete substitute for solid information.

In this day of simple panaceas, we are informed that an apple a day will keep the doctor away—a welcome discovery to apple growers, but apparently not accepted by the army of advertisers of a thousand philanthropic concoctions in bottles, tubes, jars, capsules, pills, tablets, and similar containers offering relief and contributing to the most popular indoor sport of the day—keeping the doctor away, or keeping away from the doctor. Yet it isn't quite true—it isn't at all true—that he who is his own doctor has a fool for a patient. For one of the rewards of making a friend of the doctor is to increase one's expertness in being one's own doctor, in getting something of the doctor's own view of health. Health is a cooperative enterprise, no less than education. Speaking from long experience in the classroom, I am aware of the successful resistance which many students can maintain toward the educative process; a like adroitness or attitude toward the doctor would defeat the most benevolent as well as the wisest member of the healing profession.

AIMS OF PROFESSIONAL MEN

I interject by way of a slight detour that a profession is distinguished from a business in that it is devoted to its own destruction. Its major purpose is organized suicide. The medical profession is perhaps the most professional of all. The goal of the doctor is to have all people so well that no one will have any need of him. The professor is a close second. He would like to have every one so well informed and so naturally wise that there will be no need of teaching, and he may then devote himself with the same luxurious salary to some more profitable enterprise. The minister would like to see all humanity so naturally seeking the road to salvation and so universally virtuous that his would be the most unnecessary of callings. As to the lawyer, I have my doubts: whatever concerted efforts lawyers are making to diminish human contentiousness and thus have their occupation gone is successfully concealed, and in their zoological tolerance they accept fees with equal resignation from lions and lambs, after which they have no objections to their lying down together in peace, awaiting the millenium. Let us professional men cheerfully accept the high privilege of spending our efforts in the cause of diminishing the need for our services. Yet in any future as yet foreshadowed, the psychologist may continue his observation of doctors, for there will be urgent and abundant work for both.

---

* Read before the American Laryngological, Rhinological and Otological Society, *Atlantic City, N. J., May 26, 1927.*

As one turn, whether good or not, leads to another, I add a further detour by way of a retrospective glance. That the soldier, next to the hunter, is the oldest of occupations in the total business of living, and both destroy life, is hardly a source of philosophic satisfaction. The defense against the human animal seems to be the fundamental prerequisite to life, liberty and the pursuit of happiness, endangered by the presence of other pursuers of the same goods. Next came the medicine-man, in those unspecialized days combining the functions of doctor and priest and scholar, versed in all the tribal lore of the wonder-working class, who alone could stand up against fate to avert disaster or invite if not command success. Just who has inherited his bag of tricks and assumption of superior wisdom, whether doctor, professor or minister, it would be injudicious to suggest. But their remote composite prototype had the advantage of treating the whole man, with such body, mind and soul as he possessed; and mental medicine is as old as drug-craft and bone-setting. The doctor has been for so many generations under the strain of appearing wiser than he is that we have forgotten that the word "quack" has no inherent medical restrictions. One of the incidental advantages of specialism is the relief that it affords to the general practitioner by making it respectable to admit his own limitations. The cultural route from the medicine-man to the medical specialist is a long one, full of interesting episodes, and is so largely a double story, the one of the recognition of ailments and skill in their control, and the other the reaction of the patient to the ceremonies of the healing cult, that it belongs equally to medicine and to psychology. It justifies the use of the term psychologic medicine in more senses than one, and mitigates the irrelevance of my presence in this gathering of specialists.

RELATION OF PHYSICIAN AND PATIENT

Though what I am converging on is the psychology of the doctor-patient attitude, that has its basis in the central and far-reaching fact which affects the art of the practitioner, the intricate and often baffling interplay of the bodily and the psychic mechanisms. One of the most useful words in the scientific and practical vocabulary is the word clinical. Though derived from the accidental fact that most persons when sufficiently out of gear are sick-a-bed, the bed has as little relation to the clinical attitude as has the church, which is a structure of stone, to the invisible Church, whose ministration is the reason for the edifice. The clinical attitude toward human nature is shared by the psychologist and the physician and makes them so far kin. Somewhere I met in medieval Latin the saying that where there are three doctors there are two atheists. Their skeptical Missourian reputation seems to be an old one. If not now, then eventually, it will be true that where there are three doctors there will be two psychologists. I believe that psychology has so much to contribute to the clinical insight that its inclusion in the medical curriculum is inevitable.

Both historically and by the nature of his service, dealing with a sufficiently complicated anatomy and a superimposed and supercomplicated psychology of the patient in whom that anatomy is incorporated, the doctor is by necessity both a technician and a clinician: and it is the clinical aspect that imposes the larger human and humane obligation. The dentist (and he is the last man I would dare to "knock," for he is so ingeniously equipped to get back at you) is almost wholly technician; and one rarely makes a friend of one's dentist, not only because he has all the advantage in any attempt at genial conversation, but by reason of the general intimate indignity of his attentions. Scientifically he serves as a useful personal demonstration of the anatomic cost of evolution, and should have been summoned as a formidable witness at the belated hersey trial staged in the wilderness of Tennessee. Many escape the doctor, few the dentist. He serves also to reconcile the layman to the necessity of specialists in other parts of our physiology than are exercised in any demonstration of hospitality when we eat and talk with so much of our original equipment as the dentist has spared. The era of specialism should not throw out of focus the center of the medical art, which is the function of the general practitioner, who deals more nearly with the total patient, and sees him more soundly because he sees him whole.

The practitioner meets the normal man in a somewhat abnormal situation; he must be conversant with the ills that mind as well as flesh is heir to. He must be sympathetic with the total human heritage. The two points in the psychology of that relation that dominate, yet by their very familiarity seem to have escaped pointed attention, are, first, the component of fear, and, second, the confidential unreserve. The typical attitude of the patient is one of anxiety, apprehension. The anatomic distribution of that effect is an interesting one. Some medical man has made the generalization that in diseases above the diaphragm the patient is hopeful, and in diseases below that membranous partition of optimism and pessimism he is despondent. Perhaps the most convincing bit of evidence is furnished by the malady that has the lowest mortality rate, sea-sickness, in which the sufferers are burdened with two fears according to the measure of emotional rationality which they retain: either the fear that they may die, or the fear that they won't. The fear complex occupies the central place in the psychology of the doctor-patient relation. This fact should be frankly faced; and following the clinical clue, it leads directly to the condition called neurasthenia.

THE NEURASTHENIC COMPLEX

The study of the functional nervous disorders contributes an important chapter to psychology. They stand as the end-terms of types of deviation from the normal. They are of importance for an understanding of the human composite. Parents, teachers, employers, social workers, ministers, doctors, those who in any capacity have to direct the whole man (and here it is particularly important to add the whole woman or boy or girl) must be conversant with the pictures of the liabilities of "nerves." We call them nervous disorders. They are, in fact, slightly abnormal tendencies, which, when seen through the magnifying glass of disease, show their distortions, but looked at through the other end of the opera-glass, these neuroses appear in miniature in the normal. They then represent a disposition, a tendency—what for the lack of a more convenient name we call a symptom-complex. The picture of neurasthenia in the normal person is a trait-complex; it applies to a certain type of personality. When the neurasthenic temperament is exaggerated and breaks bounds by the ravages of disease, we have clinical neurasthenia. The same principle applies to the hysterical temperament, or to the paranoid temperament, and to others not so readily differentiated. There is enough of all this in most of us, fortunately not in all of us, that illness brings out the liability. Most patients, in addition to their troubles of a more technical type, are clinically somwhat neurasthenic. In acute neurasthenia these symptoms more completely dominate and enlarge if they do not actually create the physical aches and pains and incapacities, terrorizing the patient whose misery is so profound that only a serious impairment can be held responsible. To expand this thesis would develop it into a lecture and arouse your latent neurasthenia, for its dominant symptom is fatigue. Were it not that animals share this physiologic accomplishment, I should be tempted to regard as the most characteristic human response that of yawning. It remains so in that only a human being yawns when bored as well as tired.

When the psychologist looks at a neurosis, he is on the search for a group of central factors around which the total picture may be built. For neurasthenia the first of these is fatigue—that well known tired feeling, the reputation for which the business man cultivates as an excuse for indulgence or grouch, and the really busy man, like the doctor or the psychologist, knows too intimately to need to have it described. Fatigue is the deadliest foe to happiness, the damper of success, the discourager of enterprise, the closest ally of disease in that it lowers resistance; its dominance makes rest the most universal prescription of nature, thus once more bringing the bedside as the condition of restoration. The lowering of energy conditions the lassitude that marks the departure from normal well being. We are as well as we are energetic.

The second feature is fear. The extent to which fear may incapacitate the strongest man, once his nerves are shattered, defies belief. Shell shock is fear shock. Among the war records there is one of an officer with distinguished service medals who, on his return to Washington, locked himself in his office and wept like a child in order to gather courage enough to get his discharge and live for two years alone on an island in the Pacific in an attempt to regain his nervous stability. When a man has been decorated for courage under the most trying circumstances, one ceases to think of fear as a cowardly symptom; it is definitely a neurotic one. It extends to apprehension, to worry, to care, to an incapacity to face even ordinary situations. Now there is something of this in miniature in every disease, and naturally it centers about the fear of suffering, of incapacity, of an uncertain future. The technic of assurance is accordingly the first instrument to put in the first-aid kit of the doctor. To induce by the art of authority, of reason, of persuasion, of suggestion, as normal an attitude to the acceptance of the disorder—this is what one might call clinical morale. And as the behavior of the soldier individually and collectively depends on the morale of the organization, the psychologist urges on the doctor the study of clinical morale. Its central principle must be directed to the diplomatic handling of fear. Fear is a poor name for so rich a psychologic product, and we are too apt to associate it with its more limited physical aspect. To assure by authority, to encourage by manner, to restore the broken morale which is so frequently an accompaniment of lowered health that it is one with the total ailment, that is part and at times the best part of a cure. The details belong to the practitioner of the healing art.

The third feature in the neurasthenic complex is depression. The physicians who first diagnosed the neurasthenic state labeled it by what most impressed them. Like much else of destructive value in life, it is an American invention. Dr. Beard spotted this modern devil and gave it its name, which was soon popularized as nervous prostration. He was impressed with the paralysis of energy, the overwhelming difficulty in action; while the French neurologists were more impressed with the depressive aspect, and the popular French name for it is a depression of the nerves. It is easy to understand how inevitably fear and worry, combined with difficulty in effort, lead to a complete pessimism, a true melancholia that has only the relief of moving up and down the misery scale, and in a measure yields to the solace of sleep and drug action. Thus clinical morale sends the doctor to another chapter in psychology, the study of emotional fluctuation, which finds its completest picture in the varieties of depression. The technic of meeting depression is not the same as that of meeting fear, and the resources at command are limited. To steer between stimulation that cheers but does not fatigue, which may induce a relapse, is a delicate art. The social factor so dominates the emotional life that the question is more often not what is best for the patient but who is best. Some patients like nurses; some regard them as the worst feature of the disease.

The fourth focus of neurasthenia is the loss of an allied affect, the zest, the joy of living. It is in truth merely another phase of depression, but so distintive that it is often the symptom that brings the patient to the doctor. Dr. Meyerson is so impressed with this factor that he prefers to speak not of neurasthenia, but of anhedonia, the loss of the pleasure-sense. It is one of the most dismal consequences of exhaustion and reaches from the loss of appetite to the lack of pleasure in nature, in recreation, in reading, in friends, even the interest in one's pet enemies; one becomes dull to the field of either excitement or amusement. The neurasthenic ceases to care. The anhedonic is blasé not from having tasted all life with such excess that it has grown stale, but because his energies are so lowered that nothing is worth doing. To restore energy restores control, dissipates fear, lightens depression, imparts zest. It is all part of one's morale, and it enters into the picture of disease so intimately that it stands as the guide to clinical diplomacy. It makes quite definite the state of mind that the clinician has to meet. He faces, according to the disposition of the patient, a slight or a marked neurasthenic impairment as the typical concomitant of disease. He should be prepared in the technic of its detection, its quality, and in the difficulties of its treatment. Least of all should he disregard it as of slight consequence because of the necessary major attention to the part of the disorder that he discusses with the consultant physicians.

THE GAME OF HEALTH

I pass to the second of the two reflections which come to the psychologist as he ventures to speak to as well as to look at the doctor. It is the relation of confidence and unreserve. It is the matter of throwing off the mask, or, to recognize the present fashion, the make-up which society requires all of us to wear and of establishing that more intimate footing which is indispensable in the companionable journey along the road to health. It is here that a minor aspect of the freudian psychology has a definite clinical bearing. Freud calls attention to the veil which the artificial relations of society throw over the realities of human nature. In the presence of others, every one is a censored as well as an inhibited version of himself. Those who believed that the psychoanalytic technic had a large clinical importance were influenced by the hope that this would be a method of breaking down such resistances and getting at the submerged, concealed, suppressed difficulties which at times were responsible for maladjustment and disorder. I cannot take time to indicate in any precision what portions of the freudian doctrine seem to me of permanent value. I can only say that I regard it as fortunate that only a small proportion of patients, and a still smaller proportion of normal persons, are sufficiently complex in their make-up to require or benefit by any technical psychoanalysis. Fortunately civilization has not as yet brought us to such a pass that we are all so sophisticated and involved that a doctor who is a bit of a psychologist can't see through most of his patients. He needs no more penetrating roentgen ray than common sense refined to a clinical gift. The majority is still of the ordinary garden variety of human folk, fortunately exempt from psychoanalysis because there isn't enough in them to psychoanalyze. Commonplaceness, not to say dulness, has its advantages. One of the temptations of the doctor's office to a certain type of patient is the hope that he, or should I risk all hope of popularity by saying she, may prove to be an interesting case. It is a common observation that persons with no conspicuous intellectual resources take a peculiar pleasure in discussing their ailments after the topic of the weather has been exhausted. But it is not this phase of the danger of substituting disease-consciousness for health-consciousness that I have most in mind. We are all familiar with the classic story of the medical student who, after listening to the various symptoms associated with the entire range of diseases, found that he had them all, and was only puzzled by the one exception—his failure to show any symptoms of "housemaid's knee."

Before dismissing this reference, I must use it to indicate that the peculiar domain of the freudian psychology likewise illustrates the relation of a functional nervous disorder to a temperament, for its clientele is centrally that of hysterics. From the present approach they may serve as the other pole of nervous deviation. For despite their overlapping symptoms, the technic of normalizing an hysterical patient is quite the reverse of the normalization which is the cure of a neurasthenic. The masquerades of hysteria are a challenge to the clinician and force him to be an alert technician relying on objective tests, force him to treat patients as well as diseases. The psychoanalyst has directly aimed at establishing a relation of unreserve, of breaking down resistances, though it is an open question to what cases his technic properly applies. Whatever his technic, the clinician faces the task of establishing a combination of assurance, confidence and confession. It is something more than a confidential relation, which for that matter is shared by one's lawyer and one's bootlegger. Its peculiar quality in the doctor-patient relation is that it includes the frankness of discussion which breaks down reserve. The patient must somehow be induced to bare his psychic nakedness as he bares his body to the doctor's examination, and with equal absence of anxiety that he will lose social caste by the exposure. It is a confessional relation, and completes the circle in that it is confiding as well as confidence that removes fear. The friendliness of informality is one of the most potent salves. The doctor can well afford to lose his dignity to win his patient. To discover that even a doctor is human is a tonic. It is asking too much to require a patient to recover from an illness and from the doctor's visits also. The office atmosphere leaves something to be desired in the way of inducing a sympathetic approach; nor should the reading matter displayed in the dreary waiting room for the benefit of the impatient patients suggest that it has been selected for a peculiarly intelligent group of morons. Patients are not as critical as psychologists, but it won't do to forget that while the doctor looks at the patient the patient also indulges in the privilege of looking at the doctor. It is not altogether a one-sided clinic, and perhaps it is fortunate that patients do not keep a case-book. Health is a game that two must play.

RATIONALISM IN DOCTOR-PATIENT ATTITUDE

I have suggested that in the clinical relation there must be something of love as an offset of fear and something of faith as an assurance of confidence. But we have come on days when neither love nor faith is blind. Both have been rationalized, and it is the rationalism in the doctor-patient reciprocity that sets my concluding note. It is a far cry back to the medicine-man in the rôle of wonder-worker, imposing on as well as administering to the credulous. So complete is the change that a feature of our times is the syndicated doctor. Perhaps he has the largest practice of any of you, unless it be the unrecognized practitioners, who by appropriating first our common title, science, then your special one, health, introduced a new variety of keeping away from the doctor by the original device of absent treatment. The daily health column, despite its limitations, is a favorable omen of interest. It proceeds on the correct assurance that the health attitude of the people is a public concern. How far it contributes another variety of the game of keeping away from the doctor is open to question. Bringing health doctrines to the masses, if responsibly done, is an aid to rationalizing the doctor-patient relation. It is in another column of the newspaper, which, far from paying the doctor for his contributions, receives pay from the so-called doctor, that danger lies. The advertising doctor is so far from meeting the professional standard of reducing the need for his occupation that he employs the technic of fear to frighten his victims into illness in order to collect a fee for their ransom. I infer that these adepts are especially good life-insurance risks, as none of them are in the doctor business for their health. The exploitation of the fear of illness and the fear accompanying illness is a sorry business, proving how far we still have to travel on the road to rationalism, which is also the path to humanitarianism. The psychology of the fake doctor who is also the scarce doctor is as sound as its morality is rotten.

But the advertising menace tells only part of the story. The situation is far more complicated and more serious. It is because there is a parasitic body that copies the rational technic of its host that it becomes formidable. The pseudoscience surrounding medicine operates not in the slums but often among the imperfectly educated and announces discoveries startling in claims and with testimonials galore. This body of self-made specialists not merely profess to cure and offer testimonials with alphabetical decorations to their names and short-order diplomas, but they have all discovered a *system.* That's the magical word, the rationalist slogan of the modern medicine-man. Dr. Fishbein has branded them as no layman would dare, Medical Follies; and so abundant is the crop that he has issues a supplement of New Medical Follies. All this is the penalty of the malpractice of rationalization—not the little learning, but the false pretense of learning that is a dangerous thing.

The varieties of medical follies are a testimony to human ingenuity in devising irrational appeals to reason. Their grotesque manipulations and parodies of laboratory procedure are as elaborate as they are confusing. It is asking too much of the lay mind to resist their claims when doctors must use their critical powers to distinguish between truth and presumptuous error. Perhaps they reached their climax in the lucrative genius of the late Dr. Abrams, who set forth that, by physiologic reaction registered on royalty-bearing apparatus, he could establish a differential diagnosis between a Presbyterian and a Baptist. Some of the leaders and perhaps more of the followers of medical side-shows may be sincere but deluded, but the sincerity is dilute and the delusion pays. Where ignorance is so easily capitalized it may be folly .to be wise and poor. I am using the illustration to make clear the difficulties in rationalizing the doctor-patient relation. The patient is the public, and education in the health attitude is taking its place in our general program.

I must limit my reference to one phase of this menace, the menace of cults. Cults spread, like infections, from a series of centers, and the psychology of mental contagion, when there is poor intellectual resistance, gives great power to one enterprising crook or one energetic paranoiac to become the founder of a system of healing, from walking barefoot in the wet grass (which in these dry days may be an innocent compensation) to having the kinks taken out of or put into your spine, when the real trouble is above the ears.

But a still more pertinent reason for citing the medical follies is to indicate a further kinship of the doctor and the psychologist, in that their only rivals are the Psychologic Follies. Enlarge your Personality! Develop Your Hidden Powers! Overcome Hesitation! Be a He-Man! Aid your Memory! with Health thrown in free in each and every package of Success, and all in the name of Applied Psychology. Priests and Priestesses of the Personality and the Efficiency Cult gather huge audiences in all large cities, register pupils, confer certificates, gather shekels, and move on to pastures new.

Psychology and Medicine share this unsavory field of philanthropy that thrives with peculiar vigor on American soil. How to deal with health crooks and health cranks is no different a problem than how to deal with mind-crooks and mind-cranks. Prohibition has never been an ally of rationalism and, as often proposed, is but a skepticism of education which is the only salvation: to educate the average man out of the reach of fads and cults as well as crooks. That a sucker is born every minute is an arrangement of nature against which it is idle to protest. The sad thing is that a crook is born every hour to take advantage of his fifty-nine contemporaries; and as yet even doctors have not developed a selective birth control that will correct this proportion. Kittens have their eyes open after the first two weeks of life; the human prolongation of infancy into late maturity delays this ophthalmologic operation until far too late.

Toward the problem of rationalizing the health attitude of the patient, which is so much the same for doctor and psychologist that the two are threatened by the same menace, I have time to offer but one suggestion; and it is an ancient one. *Mens sana in corpore sano.* The Romans used the same word for bodily and for mental health; mental hygiene isn't as new as we think it. We still follow the same usage: Sanity and sanitation are derived from the same root; and I think it was Mark Twain who suggested that a doctor was just a more complicated variety of janitor or plumber. There is a wholesome, well adjusted attitude toward one's life work that is the combined issues of sanity of mind and sanity of body, as similarly we associate personal and moral cleanliness in a common hygienic principle. The dissipation of fear, the establishment of confidence, the cooperation of a rational view of the mechanisms of health, suggest an outline of clinical morale.

New and Nonofficial Remedies

BISMARSEN

Preliminary Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following statement. W. A. Puckner, Secretary.

Bismarsen is the name given by the Abbott Laboratories to a new derivative of arsphenamine containing bismuth and proposed for use intramuscularly in the treatment of syphilis. Bismarsen is the sodium salt of a bismuth derivative of arsphenamine methylene sulphonic acid (sulpharsphenamine), the exact structural formula of which has not been established.

A study of the therapeutic usefulness of Bismarsen has been made by Drs. Stokes and Chambers, who read a paper on this subject before the Section on Dermatology and Syphilology at the 1927 session of the American Medical Association. A summary of this report (based on study of 110 patients treated with the drug) was submitted to the Council by the authors. Their conclusions are, in substance, as follows: The drug is an effective spirillicide, meeting requirements for the protection of public health in this matter. A few patients (perhaps 6 per cent of those treated) cannot take it because of local reaction. Its immediate effect on the blood Wassermann reaction in early cases (i. e., influence on the infection as a whole) is comparable to that of standard combined treatments now in vogue, with the added advantage of greater simplicity and lower toxicity. The drug is well borne by children in adult doses (three cases, from 5 to 6 years; two cases, from 12 to 14 years). In all types of cases it seems to have marked tonic effects. The route of administration and relative freedom from Herxheimer effects make it an acceptable drug in cardiovascular syphilis. Its doubtful points thus far include its effect on the serologic picture in established neurosyphilis, for which the authors state that their material is insufficient for conclusion as yet, and its ability to reverse resistant positive blood Wassermann reactions and to hold negatives unaided.

The manufacturer has submitted two letters as evidence for the value of the product, one from Dr. John A. Kolmer of Philadelphia, the other from Dr. C. H. De T. Shivers of Atlantic City: Dr. Kolmer reported in an informal and preliminary way that he was favorably impressed with the drug from its use in the treatment of fourteen chronic cases, including three of congenital syphilis and four of acquired "Wassermann-fast" syphilis; Dr. Shivers reported in much the same manner his generally favorable impression from the use of a drug designated "X. Y. S." (presumably Bismarsen) in 140 cases including primary, secondary and tertiary syphilis. No formal case reports accompanied either of these letters.

A supply of the drug was sent to one of the Council's consultants, who makes the following report:

"It has been our object to study the effect of the drug on the spirochetes of local lesions, for, after all, this gives probably as good a criterion of the value of an antisyphilitic remedy as anything that we have.

"We have studied thirteen cases which have been in the hospital under closest observation, where we have been able to make dark-field examinations on the patients every day. The material has consisted of three patients with primary lesions, and the rest of them with mixed primary and secondary or secondary lesions of syphilis.

"Our technic has been to start with an injection of 0.1 Gm. and if the patient stood it all right, to give 0.2 Gm. and to use the remedy about every three days. With some of the later cases we used it even every two days and with some of them we raised the dose to 0.3 Gm. at an injection. The number of doses given in these thirteen cases varied, with extremes of three and twelve injections, and a median of seven injections; and the total amount of drug given has varied, with extremes of 0.5 Gm. and 2.2 Gm., with a median of 1.2 Gm.

"We have not noticed any symptoms of toxicity in connection with this preparation systemically, nor have we noted any evidence of skin eruption or evidence of a Herxheimer reaction following the injections, even in cases of secondary syphilis with marked generalized eruptions.

"As far as pains from the local injections are concerned, this was noted in quite a few instances, and in three of the patients this pain was very severe. We have a notation that one of the patients complained bitterly, and in two of the patients it was necessary to stop the injections, in one of them after three injections and in another after four injections; while still another patient complained that the pain was very severe for thirty-six hours after the injection. This was used in doses of 0.2 Gm., and not higher. Still another patient, whom we do not have down in this list of those that complained so bitterly, reported that with the first five injections there were severe pains, but with the last four the pain was not noted so much.

"*Results*.—In one patient with a generalized papulosquamous syphiloderm, with three injections, a total of 0.5 Gm., there was quite a good clinical result and the eruption seemed to clear up quite rapidly, including the condyloma, though the spirochetes did not disappear from them for seven days.

"In still another patient with a sparse papular eruption that was just beginning, the eruption seemed to have disappeared after about a week of treatment.

"*Disappearance of Spirochetes*.—In ten of the patients it was possible to follow the clinical results by examination for spirochetes in the local lesion, and these patients were followed daily and very careful examinations made. The spirochetes disappeared in extremes of three days and twelve days, with a mean of between five and six days.

CONCLUSIONS

"We believe that this preparation has a certain amount of merit, and there may be certain situations in which it would be of value to have some such remedy as this to fall back on."

The foregoing reports are obviously insufficient to form the basis of acceptance of the drug for New and Nonofficial Remedies. Further trial and confirmation are needed before more than tentative acceptance can be accorded. However, the generally favorable character of the reports together with the fact that Bismarsen is a chemical substance of controlled composition is sufficient to warrant its further trial by physicians, with due recognition of the fact that the drug is still in the experimental stage. The Council has, therefore, deferred acceptance of Bismarsen and authorized publication of this preliminary report.

For the information of those who desire to use this compound, the following description is published:

BISMARSEN.—Sulpharsphenamine Bismuth.—Bismuth Arsphenamine Sulphonate.—The sodium salt of a bismuth derivative of arsphenamine methylene sulphonic acid (the exact structural formula of which has not been established) with inorganic salts. It contains approximately 13 per cent of arsenic and 24 per cent of bismuth.

Actions and Uses.—For the treatment of syphilis. According to Stokes and Chambers, the drug is somewhat slower in its action than intramuscularly administered sulpharsphenamine or intravenously administered neoarsphenamine, but much more rapid than bismuth; and it has marked "tonic" properties. More or less severe pains at the site of injection have been reported.

Dosage.—Bismarsen is administered intramuscularly. The initial dose is 0.1 Gm.; for succeeding doses Stokes and Chambers used 0.2 Gm. each of the drug dissolved in ampule with 1 cc. of sterile distilled water at the time of administration, adding to the solution 2 to 3 drops of a 2 per cent solution of butyn. At the time of reporting, however, the authors questioned the desirability of using the local anesthetic. Weekly increasing to biweekly doses were used in treatment courses of twenty doses.

Manufactured by the Abbott Laboratories, North Chicago, Ill. U. S. patent 1,605,691 (Nov. 2, 1926; expires 1943). U. S. trademark applied for.

Bismarsen is prepared by adding a solution of potassium bismuth tartrate in water to an aqueous solution of 3,3' diamino 4,4' dihydroxarsenobenzene N,N' dimethylene sulphonate, dissolving precipitate with a measured quantity of sodium hydroxide solution, precipitating by pouring the clear solution into a methyl alcohol ether mixture, filtering off the precipitate and drying it in vacuo.

Bismarsen is a brownish yellow amorphous powder readily soluble in water, yielding a yellow solution which is slightly alkaline to litmus.

Add 2 cc. of diluted hydrochloric acid to 5 cc. of a 1 per cent solution of bismarsen: a white opalescence appears and dissolves almost immediately; a heavy white gelatinous precipitate develops in two minutes. Add 1 cc. of diluted nitric acid to 5 cc. of a 1 per cent solution of bismarsen: the solution gradually turns brown and yields a precipitate. Add 1 cc. of trinitrophenol solution to 5 cc. of a 1 per cent solution of bismarsen: no apparent reaction takes place (*distinction from silver arsphenamine and potassium bismuth tartrate*). Bubble hydrogen sulphide through a 1 per cent solution of bismarsen: the solution darkens immediately but no precipitate is formed. Add 5 cc. of hydrogen peroxide solution to 5 cc. of a 1 per cent solution of bismarsen: the solution is at first turbid, then becomes a deep reddish brown with formation of a precipitate. Add 1 cc. of mercuric potassium iodide solution to 5 cc. of a 1 per cent solution of bismarsen: the solution yields a greenish yellow opalescence, which in turn assumes a dirty green color on standing. Add drop by drop 2 cc. of a 40 per cent sodium hydroxide solution to 5 cc. of a 1 per cent solution of bismarsen: the solution gradually darkens without any formation of precipitate. Add 0.5 cc. of a 2 per cent silver nitrate solution to 5 cc. of a 1 per cent solution of bismarsen: a dark red solution is produced (*distinction from arsphenamine*). Add 1 cc. of a saturated solution of bromine in water to 5 cc. of a 1 per cent solution of bismarsen: the solution yields a greenish brown precipitate (*distinction from sulpharsphenamine,* [illegible] *and arsphenamine*). Add 0.5 Gm. of zinc dust and 5 [illegible] acid to 0.1 Gm. of bismarsen in a test tube, [illegible] hold a strip of filter paper moistened with 5 per cent cadmium chloride solution: the paper turns yellow in four minutes.

Transfer about 0.4 Gm. of bismarsen, accurately weighed, to a Kjeldahl flask, add 2 cc. of sulphuric acid and heat carefully; add 2 cc. of nitric acid a drop at a time, continue heating until brown fumes cease to be given off, cool and add water to make 120 cc.; if a white crystalline precipitate appears dissolve it with a few drops of hydrochloric acid; transfer to a 250 cc. beaker, add 7 Gm. of tartaric acid, neutralize with stronger ammonia water, add 10 cc. of magnesia mixture followed by 20 cc. of stronger ammonia water, allow to stand twelve hours, filter through a hard surface filter paper and wash the precipitate with 50 cc. of 2.5 per cent ammonia water, puncture the filter, transfer the precipitate into a 250 cc. beaker with washings, then add just sufficient hydrochloric acid to dissolve the precipitate, filter, wash the filter well with water, neutralize the filtrate with stronger ammonia water; add 1 cc. of magnesia mixture and 20 cc. of stronger ammonia water; allow to stand twelve hours; filter, using a prepared Gooch crucible; wash with 2.5 per cent ammonia water; dry at 100 C.; ignite at 700 C. for three hours; cool in a desiccator and weigh as magnesium pyroarsenate and calculate to arsenic: the arsenic content is not less than 12.50 per cent, nor more than 13.50 per cent. Transfer about 0.25 Gm. of bismarsen accurately weighed to an Erlenmeyer flask. Add 5 cc. of diluted sulphuric acid followed by 1 Gm. of powdered potassium permanganate, and 10 cc. of sulphuric acid in small portions; add just sufficient hydrogen peroxide to dissolve the brown precipitate; add 50 cc. of water; boil for twenty minutes; cool to 70 C.; saturate with hydrogen sulphide for twelve hours; filter using a prepared Gooch crucible; wash the precipitate with water, warm ammonium polysulphide, methyl alcohol, carbon bisulphide and acetone in the order named; dry at 100 C.; cool in a desiccator and weigh as bismuth sulphide (Bi_2S_3); calculate to bismuth: the percentage of bismuth found corresponds with the percentage of arsenic found multiplied by 1.86 (factor As to Bi in [illegible]Na_3S_2[illegible]Bi_2) plus or minus 0.5 per cent.

WAR GASES AND TUBERCULOSIS

Those who would remind us that "a very large proportion of the misery borne by mankind is man-made" turn nowadays to experiences of the World War for their illustrations. They cite the epidemics that have followed in the trail of the great combat, the unexpected awakening of diseases that have long seemed to be dormant, and the widespread dissemination of objectionable parasitic forms of life into regions where they have been practically unknown. All these features have furnished new jeopardies and increased the obligations of public hygiene. But the recent conflict also created some entirely novel health-disturbing situations that could scarcely have been foreseen. Notable among them were the effects of the so-called war gases. The distressing immediate symptoms of gassing with their excruciating torture left in their wake the possibilities of prolonged deterioration of health. Invalidism and a comparatively early death were expected as the aftermath of the use of the newest weapons of war.

When the toxic gases were thus introduced it was, as Koontz[1] has pointed out, the natural reaction of the layman, as well as of the physician, to believe that their effects on the lungs would cause a predisposition to pulmonary tuberculosis. This early conclusion, hastily arrived at before there were any facts available for affirming or denying it, Koontz adds, has remained largely fixed in the minds of laymen, and also in the minds of a considerable number of physicians. It was also expected that old tuberculous lesions might become reactivated. A decade of post-war clinical observation has, in general, failed to substantiate the quite natural early expectations. Many, probably most, of the critical examiners of the survivors of war gassing will agree with Meade's[2] conclusion that "a man is no more liable to tuberculosis as the result of gassing than is a man who has never been gassed." A similar conviction, voiced by many writers, was thus expressed by Francine:[3]

> It is inconceivable that gas (as it is, and not what so many people consider it to be, or what it may have been) could reactivate tuberculosis, and available statistics and majority expert opinion go to prove that it does not do so. This view is endorsed by French, British and other authorities.

The almost complete unanimity regarding the clinical observations is supported by additional direct experimental evidence. For example, Koontz, the pathologist of the Medical Research Division of the Chemical Warfare Service, has made extensive tests on suitable animals. They demonstrate clearly that rabbits gassed with phosgene, mustard and lewisite are not more susceptible to tuberculosis than are control animals inoculated at the same time with the same dose of bacilli. The gassing of animals that already have well developed tuberculosis does not appreciably accelerate the tuberculous process. There are even some indications of occasional protective or ameliorating effects of gassing on the tuberculous processes. It is thus fortunate, indeed, that some of the early discouraging expectations of the devastating effects of the war gases have not been realized.

THE LIMITATIONS OF SCIENCE

In a discussion of some current tendencies in the promotion of chemical research, Mendel[4] of Yale University has uttered a frank warning against certain possible dangers in the present-day undue vaunting of the contributions of science to the welfare of mankind. He reminds us that the recent popular exaltation of physics and chemistry is in part due to the help which these sciences in particular furnished in the prosecution of the World War. As a consequence the sciences have come to be regarded by many as forces to conjure with—potencies for affording a solution to almost any question that is presented to the devotees of science. Of course, as Mendel points out, men of science realize that they cannot answer the riddles of life or solve the problems of industry on command; yet the larger public is beginning to assume that in the scientific disciplines a little enthusiasm and well directed energy will inevitably furnish the required solutions.

The physician is not unfamiliar with a comparable attitude in relation to the medical sciences. Perhaps there is a real compliment to research medicine expressed in the confident hope that a well equipped laboratory with a devoted investigator can promptly overcome all the barriers that cross the path to knowledge. However, scientific progress usually represents slow growth. Even diligent protracted effort does not invariably lead to the desired goal. "Disappointment turns to disillusionment and then to distrust. When this occurs science is in danger of losing many an ardent admirer and perhaps not a few staunch supporters." It is not only the layman who is not inured to the frequent shortcomings of experimentation; the physician, too, may expect that a test tube or a beaker in the hands of a "laboratory worker" will surely give him the desired clue to some mystery of diagnosis; and like his untutored patient the practitioner may react with subsequent indifference to scientific methods if perchance the investigator has failed him a few times.

[4] Mendel, L B Some Tendencies in the Promotion of Chemical Research, Science 65: 559 (June 10) 1927.

The scientific worker must have his courage sustained. As Mendel has remarked, joyous as it may be to acclaim the triumphs of science, is it not also desirable to educate the auditors with respect to the ways and means, the trials and errors, by which alone continued and permanent contributions are assured? The recognition that knowledge is finite, that progress involves change, that traditional beliefs are subject to revision, needs to be promoted. In medical research, as in other fields of science, failure in one endeavor should lead to fresh effort and new attacks on the unknown. Those who are engaged in the work are quite as likely to be discouraged by the undue expectation of others as by their indifference.

VISCOSITY OF THE BLOOD IN SHOCK

Shock has been described as a condition in which there is more or less paralysis of the sensory and motor portions of the reflex arc, with profound disturbances in the circulatory system, subnormal temperature, and frequent and shallow respiration.[1] This formidable array of symptoms is not more portentous than the distressing phenomena encountered not infrequently in clinical experience. Although the subject can scarcely be said to have required new interest to promote its investigation, the medical problems of the World War focused attention on it. Perhaps the most significant outcome of the war-time investigations was the growing conviction that shock is not an *individual* entity. Whenever some single conspicuous etiologic possibility was critically considered, other causative factors would present themselves for equally serious recognition. They have been rehearsed from time to time in The Journal. Today it is probably reasonable to conclude that shock is due to a variety of causes, some of them, however, claiming a greater practical significance than others. One may read of hemorrhagic shock, anesthetic shock, toxic shock, nervous shock and, in particular, surgical shock, each demanding somewhat special consideration.

The symptoms of these various conditions may be differentiated into those of primary and those of secondary importance. The fall of blood pressure has always been a prominent manifestation, inevitably bringing with it a train of disagreeable sequences. The decrease in arterial tension may be attended by an accumulation of blood in the liver and larger veins of the abdomen, so that the condition has actually been referred to as a "bleeding into the veins of the abdomen." For this, failure of the vasomotor mechanism, "capillary poisons," and increased peripheral resistance, among other factors, have been held responsible. The most recent theory to strive for recognition has been formulated by Waud.[2] In an experimental study of anaphylactic shock as well as the shock resulting from injection of certain toxic agents, he has noted an unmistakable reduction in the viscosity of the blood. Ten years ago the late Sir William Bayliss[3] showed that a 30 per cent reduction in the viscosity of the blood, produced by a withdrawal of blood and its replacement by an equal amount of saline solution, is accompanied by the same percentage reduction in blood pressure. Waud argues that the reduction in viscosity causes the fall in blood pressure because of the fact that the less viscid blood passes through the small arterioles more readily, and thus the pressure and blood volume in the capillaries are suddenly increased. If the reduction in viscosity applies also to the endothelial cells of the capillaries, it may conceivably become a contributing factor in the production of edema in shock. There is experimental evidence to show that a lowering of the viscosity of the cell surface results in more rapid diffusion of substances through the cell. Accordingly it would be plausible, in Waud's opinion, to conclude that the initial lowering of the viscosity of blood in conditions of shock may be associated with a lowering of the viscosity of the surface layer of the endothelial cells of the capillaries, thus allowing a more rapid passage of the fluid contents of the blood into the tissues, and thereby increasing the amount of fluid in them.

TESTS OF CIRCULATORY FITNESS

The examination of the cardiovascular reactions of persons has become a conventional method of estimating something of their physical fitness. In the clinic the same principles have been applied to determine, for patients with circulatory deficiencies, the extent to which various forms of physical exercise may be warranted; likewise the improvement or the reverse that may attend the progress and treatment of the disorder. In the tests proposed by Schneider[4] of Wesleyan University the data employed are the pulse rates during recumbency and standing, the increase in the frequency of the heart beat when the standing and reclining postures are compared, the acceleration of the pulse rate by a standard exercise, the time required for the pulse rate to return to normal after the exercise, and the change in the systolic arterial blood pressure when a change is made from recumbency to standing. It is believed that a slow heart rate in recumbency and standing, with a small difference between the two, a slight acceleration of the heart rate in exercise, with a quick return to normal afterward, and a rise in the systolic arterial blood pressure on standing, are excellent health signs and that in the physically fit individual the heart and vasomotor system are, so to speak, tuned to a different pitch than in the unfit or unhealthy person.

In her recent studies at the Harvard School of Public Health, Turner[5] demonstrated that even in healthy persons the change from a reclining to a quiet sitting or standing posture is attended by a fall in the circulatory minute volume. This implies a common lack of perfect adjustment to the increased needs of the erect position. Turner has described the essentially difficult task of the circulation as that of getting blood to, and not from, the heart. In the quiet erect position the usual aids to the return of blood to the right heart during exercise are lacking, there is no rhythmic muscular motion, and there is little increase of thoracic aspiration. On the other hand, because of gravity, there is a difficulty in the return of the large amount of blood below the level of the heart. It is possible that the vertical abdomen with its unsupported ventral wall may account for the unsuccessful return of blood to the heart at least in some persons.

The holding of a quiet standing position through a period of several minutes is a more difficult task than has been thought by many. Turner[6] has ascertained that persons are frequently found whose circulation adapts itself with apparent ease to strenuous exercise yet who find quiet standing more difficult, as is shown by their reactions both subjective and objective. The best circulatory adjustment, such as is observed in persons well trained physically, is one in which the minute volume of the reclining position is maintained during standing. Systematic comparisons of the outcome of Schneider tests and the new Turner tests, including records of the heart rate and blood pressure involved in the response to long standing rather than exercise, indicated a fair degree of parallelism between the scores. The essential mechanical difficulties involved in maintaining the erect position suggest that tests based on the change from reclining to a more or less prolonged period of standing still are likely to yield differential results quite as suggestive as the more commonly used comparisons of exercise versus rest. Persons who stand most easily and successfully from the standpoints of objective appearance and lack of fatigue are those in whom there is a slow rate and a relatively large pulse pressure, indicating a heart adequately filled between beats. Inadequately filled hearts attempt to maintain an adequate pressure by an increased rate. Thus the low pulse pressure and the rapid rate become indicative of a low output per minute. Exercise facilitates the maintenance of the circulation in the upright position. As Turner concludes, an entirely successful meeting of the circulatory demands of prolonged standing may be an achievement which is reached only by an apparatus capable of the most perfect and responsive adjustment to relatively slight stimuli.

FEE-SPLITTING QUACKERY

"Radithor" is one of the numerous pieces of quackery in the field of radioactivity. It is exploited by the Bailey Radium Laboratories of East Orange, N. J., the moving spirit of which is one William J. A. Bailey, whose past record with "patent medicine" concerns and a fake engineering corporation was dealt with in The Journal, January 29. The Radithor quackery consists of thirty half-ounce bottles of distilled water which is alleged to be radioactive. No less than thirty bottles can be purchased; and the price is $30. That is, the price to the sucker who happens to be a layman is $30; to the easy mark who can write M.D. after his name, it is $25. There are two order forms, one, the "Standard Order Form" that the layman fills out; the other, the "Special Order Form for Doctors' Use Only." This form states that "when patient buys direct, we allow doctor a $5 credit on all orders." The physician who would order Radithor must be weak not only in medicine but also in morals.

McCOY, HEALTH COLUMNIST

In *Hygeia* for August appears an analysis of the volume called "The Fast Way to Health," published by one Frank McCoy[1] in connection with a column of so-called health advice appearing daily in some newspapers. Dr. Hill, who is professor of bacteriology and of nursing and health of the University of British Columbia, calls attention to only a few of the more glaring crudities, medical and dietetic, that appear in the volume mentioned. McCoy is a chiropractor who now calls himself "Dr.," although he formerly headed a little private notion styled "physculpractic," presumably a combination of physical culture and chiropractic. The fact that such preposterous bilge as is contained in the McCoy opus and in the daily columns can be sold to the public is not astonishing in view of the alarming extent of ignorance of the human body and of its functions among our adult population. It is amazing, however, that editors—men supposed to have wide knowledge and a wide grasp of human affairs as well as sound judgment—would recommend the expenditure of real money for the piffle that characterizes the daily columns of health advice. Any editor who cared enough about the truth to inquire of his own state university faculty could with but little trouble find out the hopelessly fallacious nature of the statements made by McCoy and their danger in relation to the health of the public. True, Mr. Babe Ruth asserts that the McCoy statements are serviceable; but the care of a cancer of the lip is not at all the same procedure that is involved in whacking a horsehide covered sphere of rubber and twine with a four foot piece of lumber. Editors may plead public demand for the publication of the bogus diaries of Peaches Browning and the murderous Mrs. Snyder; such demand as exists for the McCoy fallacies is created by the editors themselves.

CONFERENCE ON PUBLIC HEALTH

Held in Chicago, March 24-25, 1927

(Concluded from page 123)

Economics of Public Health

Dr. John A. Ferrell, Director for the United States, International Health Board of the Rockefeller Foundation, New York.

This paper was published in full in the last issue of The Journal.

DISCUSSION

Mr. Barry C. Smith, Commonwealth Fund, New York: I suppose I have shown temerity to induce the Commonwealth Fund to enter the health field. Probably our lack of expert knowledge in the field was what led us to consult the expert and the physician. In our health demonstration program we have first a national board or committee, to which is delegated the specific directions. On that board we have five physicians, three of whom have had wide experience in public health. In approaching the question of establishing demonstrations in four local communities, in each case we have conferred not only with the local health board but also with the state board of health. In setting up the staff for those demonstrations we have in each instance put an experienced, trained public health physician, M.D., in charge, and since our point of departure was child health, we have placed the medical service in the hands of a competent and experienced pediatrician. In each case, when we have entered a community in order that there might be no misunderstanding, no friction with the practicing physician, we have early held conferences with the local medical society, and we have seen to it that the procedure to be followed in the educational and preventive work of the demonstration was acceptable to the local practitioner as represented in that society. So far as our particular demonstrations are concerned, we do not seem to have become involved in controversies as to whether the official or the voluntary health agency was to dominate or was to be subordinate. Each demonstration program has been considered not as a separate entity but as an adjunct and a part of the local health department program, and in every demonstration we have endeavored to develop the opportunity afforded the local health department, not only in the work it is doing but to the extent to which it feels it is able and desires to take over little by little the work the demonstration is doing. I think there has been a great deal of feeling (I do not mean feeling in an unpleasant sense) that the demonstrations of the Milbank Memorial Fund and of the Commonwealth Fund were spending perhaps more money than was justified because of the fear that the standard thereby set would be beyond the rest of the country. We know that when the public appreciates the value of particular material improvement, the money is forthcoming. I believe that the expenditures in the field of public health today, taken by and large throughout the United States, are as small as they are, not because the money is lacking to put on a complete program such as would really protect the health of the citizens of that area, but because the public has not yet become educated as to the importance of public health work. I expect to see the time when the average community in the United States is not going to question the expenditure of 25 or 50 or 75 cents but it is going to demand an expenditure of from $3 to $5 per capita.

Dr. Matthias Nicoll, Commissioner of Health, State Department of Health, Albany, N. Y.: Expenditures for public health are not what they should be, but I think Dr. Ferrell's statistics, certainly as regards my own state, give a false impression. New York State is in a unique position in that the care of the health of half the people of the state, numbering approximately eleven million, is under the state commissioner of health, and the other half under the New York City commissioner of health. The state legislature appropriates money almost solely for health work under the state commissioner of health and not for that in New York City. For that reason, in arriving at the per capita expenditure for public health in New York State, Dr. Ferrell should cut in two the population benefited, which would double the per capita expenditure as reported, and put us on a plane at least equal to Florida, or else add the appropriation for the New York City Health Department, exclusive of hospitals, which I believe is some three million dollars. This does not take into account the large sums spent in such cities as Syracuse, Buffalo and Rochester, which come out of the pockets of the taxpayers just as certainly as though they were appropriated by the legislature of the state. I think that if Dr. Ferrell will take into consideration all large local items expended for public health, the state of New York will come pretty near to heading the list of the states in respect to expenditures for public health purposes.

Dr. B. Franklin Royer, National Commission for Prevention of Blindness, New York: I may speak from my personal knowledge in Pennsylvania. Dr. Ferrell has specifically taken out of the appropriation that which is set aside for the tuberculosis work. In Philadelphia, Pittsburgh and Scranton and in the other large centers of population, there are practically no other expenditures of state funds.

Mr. James A. Tobey, American Public Health Association, New York: In connection with Dr. Ferrell's paper I should like to cite more recent statistics with regard to governmental expenditures. For the fiscal year 1926, ending June 30, the United States government appropriated for all public health purposes approximately $15,000,000, which is 0.5 per cent of the total national budget of approximately $3,000,000,000. As you can see, this sum amounts to approximately 12 cents per capita. The United States government still appropriates almost as much for animal diseases as it does for the public health of human beings. In 1926 it appropriated between $11,000,000 and $12,000,000 to the Bureau of Animal Industry, which sum is greater than the amount allotted to the United States Public Health Service alone, which gets around $10,000,000, of which only about $5,000,000, however, actually goes into public health work, for the rest is used for hospitalization and medical relief. The states as a whole probably appropriate about $45,000,000, that is, from official sources, including the state appropriations and those in counties and municipalities. In spite of the fact that public health under our form of government is primarily a state responsibility, the federal government appropriates one-third as much as all the states put together. Whereas the federal government appropriates $15,000,000 for public health, it appropriates $50,000,000 for medical relief, that is, for cure; in the states probably three times as much or more is appropriated for institutional work as for preventive medicine. Does it not seem reasonable that a little larger expenditure for preventive work, for public health activities, would result in a slightly less expenditure for relief?

Dr. Linsly R. Williams, National Tuberculosis Association, New York: I was interested in what Dr. Ferrell had to tell about the increase in the amount of money expended for health work. I feel convinced that if one would compare the increase expended for health work with the increase expended for almost any other branch of governmental activity, it would be found that in the other branches the increase had taken place more rapidly and was on a higher percentage basis than health work. The increase in 1919 from 63 cents to 82 cents in 1923 has not even kept up with the increase in the cost of obtaining service, which I think should indicate pretty clearly to health officers that the probabilities are the majority of their staff have not received an increase in salary commensurate with the increase in cost of living or diminution in the value of the dollar. I quite agree with Mr. Barry Smith that we have not begun to convince the people they can afford to spend a great deal more on health work, and give the health officers a fairly decent salary and a little more security of tenure of office.

Mr. James L. Fieser, American National Red Cross, Washington, D. C.: This discussion draws into the picture a third element that is directly concerned and may be called the raw material of this discussion; namely, the people who are ill and the people who wish to preserve health. It would be interesting if we could have a map which in various colors would indicate the degree of development of public health work and public health thinking in its various gradations. It would show the areas in which health facilities are nonexistent or where they are limited to the facilities of the private practitioner and the most elementary kind of hospital. One of the things that contribute to rural discontent is the fact that the facilities do not exist for the average citizen, Mr. Raw Material, in his community. What may we as agencies, public and private, and as individual representatives of a profession and as citizens do? Is that raw material something that could be harnessed up with some of these issues not in debate? This May if you go to Mansfield, Ohio, on a given date you will see literally thousands of people in town, probably 4,000 or 5,000 children in parade, with reviewing stands and bands and that sort of thing, on the subject of health. Every one of these children has been examined by physicians throughout the county, and each proudly wears its blue ribbon or whatever other index it might be, somehow epitomizing this thing. The child, for instance, that has been hesitant about a tonsillectomy is eager to have it. Of course, that goes back to the private practitioner. The child is eager to have the operation so it may participate in this parade. Of course that is show, but nevertheless it does indicate something of that potential force which in a measure we have neglected in America, that thing that represents this raw stuff, me, a layman, my wife, my child. Rotary, Kiwanis, the great orders of one kind or another, the Shrine and so forth, again with their particular grouping, constitute raw material which can be put into harness, if we have something positive to give. If we do not supply it they will initiate it themselves, because they are the victims, after all, of this whole thing. Perhaps increasingly, quietly, naturally, in national get-togethers like this, in state get-togethers and in our local and county get-togethers, representing the medical profession, health activities, the laymen of the United States and the average citizen, man, woman and child, we can begin somehow to do exactly what is shown on many of these maps and charts; namely, to increase the number of sections which carry the color indicative of a progressive thought and a united cooperative action.

Dr. S. W. Welch, Chairman, Alabama State Board of Censors and State Health Officer, Montgomery, Ala.: We ought to be congratulated on this array of statistical data which Dr. Ferrell has brought us, and there is only one phase of the question which I wish to debate, and that is the development of the poorer areas, the poor counties. That could be handled by increasing state appropriations to the point of establishing health organizations in those counties that were not able, for the time being, to establish them for themselves. It would be a wise policy, if we could all come to it, of the wealthy centers of the United States helping out those areas that are less fortunate.

Mr. John A. Kingsbury, Milbank Memorial Fund, New York: I think we would all agree with Dr. West that we should not go too fast in public health work and we should not spend too much money in any community on health demonstrations, but the two questions really are, What is too fast? and What is too much money? These are two things on which we should get together because the doctors have a different idea about them than the social workers have, and perhaps neither is right. One of the greatest demonstrations the Rockefeller Foundation has ever made endeavored to show what can be done in the poorer counties with a limited amount of money. You can get the people to spend more than they ever had any idea they could spend. I will say that practically every word Mr. Smith said concerning the policy of the Commonwealth Fund applies to the Milbank Foundation. Every move we have made has been made on the advice of the best medical men and the best health experts we could command. We are trying to find out how much a community can really afford to spend. We are trying not to spend more money than the people can eventually spend themselves. We trust we are not going too far or too fast. Let us have such a conference committee as Dr. Fisher has proposed, and find out.

Secretary West: When this conference was proposed, there was some correspondence with most of the health agencies of the country. It was clearly indicated in replies that came to our letters that some of them feared somebody was going to do something to them. That is why it was stated in the invitations sent out that there would be no voting. I can assure this body, however, knowing the Board of Trustees of the American Medical Association as I do, that they will be glad to have any suggestions that may be offered. I think Dr. Fisher's suggestion is a splendid one and it is eminently proper.

Dr. J. A. Ferrell, Director for the United States, International Health Board of the Rockefeller Foundation, New York: I anticipated the criticism of Dr. Nicoll. Of course the same criticism might come from Ohio. It has Cincinnati, Cleveland, Columbus and Toledo. California has San Francisco and Los Angeles. Any attempt to correct the figures for the various states so that the local expenditures would be excluded would prove more difficult than the task I undertook. The fact that New York City is not cared for by the New York state health department really bears out the trend of thought I was trying to bring out, that perhaps New York City really belongs to the nation. It is the principal money market; it is there that you have to have stocks transferred. Our principal shipments take place there. So New York is really a part of the nation, and I think we should so regard it. Likewise we might regard some of the other large centers of population as national rather than local assets. Dr. Welch, for example, might object to the figures for his state. I show only 8.3 cents per capita sent in Alabama, but if you will investigate you will find that more than 50 per cent of the population of the state are served with full-time county health organizations that are conducted under the general leadership and supervision of the state department of health, and toward the budget of each one the state health department makes a direct contribution; so that it is not practicable to make a complete analysis. It would be utterly impossible to take up every state and community and correct the figures. A certain amount of generalization is necessary. Representatives of certain agencies that are cooperating in the conduct of health demonstrations seem to feel they are accused of spending too much money. Much of the expenditure is for the collection of information, and there might have been less misunderstanding if these field investigations could have been designated as fact-finding field studies, rather than health demonstrations, because a considerable amount of money that is shown as per capita expenditure really goes into what is virtually research in the field of administration and application of existing knowledge to the control of disease. There has been some discussion here with regard to the relationship of physicians generally throughout the country with regard to health work. Of these 330 county demonstrations that have been established, I am more or less familiar with the conditions of approximately 200. Unless the leading local physicians had lent themselves freely and generously to aiding the health authorities, I do not believe the demonstrations would have been established. Generally the health officer, if he will present a sound program to the county medical society or to the leading members of the local medical profession, is able to get a group to go with him to the appropriating bodies of the county and get the necessary funds with which to inaugurate this work. It is a change of atmosphere to go from these counties, where these local physicians spend their time and ability and influence so generously in the establishment of some of these organizations, to certain business meetings at which the bugaboo of state medicine is so loudly cried. It does not fit in with the situation that we encounter locally. I believe some of these state health officers who deal locally with the medical organization will bear that statement out. With regard to what we are going to do in the future in regard to public health, many of us have hopes. In general, public health authorities have their feet on the ground. They are winning confidence; they are getting backing from the taxpayers, and the result in the public health movement may be cumulative. Our problems and difficulties are almost identical with those of the educators in developing a better system of public schools, and in that field they have found the problems are largely economical.

Dr. Linsly R. Williams, National Tuberculosis Association, New York: The health departments find difficulty in securing money for propaganda work, and if they do secure an appropriation of any size for health work, the pamphlets and leaflets are bound to advertise the name of the health officer. Some of our legislative bodies have become rather incensed with the notoriety gained by a few health officers and have summarily proceeded to discontinue or markedly cut down the appropriation. I do not see how it is possible, with that point of view, for health departments to get any large amount of money for educational work, and in the private associations they are limited, to a certain extent, by funds, and distribute literature frequently which they know is not printed in the best possible form and where illustrations are crude and not of the best type.

Dr. Morris Fishbein, Editor, The Journal of the American Medical Association and *Hygeia*, Chicago: The matter just brought up is one of the most important that can come before the conference. I am convinced on careful study of the matter, and not from a cursory impression, that much money is being wasted on printing by health officers, by state health officials, by voluntary health organizations and by national organizations of all types in the health field. More money is being wasted in printing than in perhaps any other form in which money is being wasted, and that even includes some of the large demonstrations. The printed material that comes across my desk as editor of The Journal and as editor of *Hygeia* indicates that a vast amount of material that is not going to be read is being issued by all sorts of organizations. The point made by Mr. Smith as to the sending and distribution of pamphlets is also important. In Chicago, Dr. Bundesen sends a letter to the mother one month after the birth of a child. This is a personal letter, announcing that one month has passed and that there are certain things to be taken into account. Another letter goes each month to the mother. In mingling with various groups about Chicago, in attending meetings of women's clubs and of all sorts of organizations, I have yet to find one group in which the discussion of health education was brought up in which the personal health literature had failed to make an impression. I mentioned yesterday a survey that had shown that there were more than 100 different books on the care of the baby during the first year published in the United States in the last three years. In those books the advice varies, from advice to begin artificial feeding at once, which everybody will agree is bad advice, to advice to fed the baby by the breast every three hours and oftener. In fact almost every possible difference in feeding the baby is brought out in these various pamphlets. Certainly the most important thing in all of this health propaganda work and health education work is in keeping public confidence, and public confidence cannot be kept when authorities, or those who presume to be authorities, disagree in simple matters. Recently in northern Minnesota the health official decided to immunize against scarlet fever every child in the community. He chose for the purpose of immunization a preparation that had not been passed on by any reliable authority as a reliable preparation. The response to this attempt was a series of letters from most of the physicians practicing in the community addressed to this office asking by what authority any public health official could immunize children against scarlet fever with a preparation not established. If one looks into the background of this situation, the probability is that a commercial house was trying to establish its scarlet fever antitoxin and persuaded the health officer to make the demonstration. This is the way in which this thing comes directly to the general practitioner in the field. He finds a divided group of interests trying to promote health education, and he is unable to make his decision as to how he shall act in his relationship to the matter. The only way to get his proper reaction is for the state health agency or the county health agency, the volunteer health agency and the physicians to get together, to agree as to the things that are to be taught, and to cooperate in putting the teachings into effect.

Chairman Heckel: Is there anything further? If not, I should like to say just a word or two for the members of the Board of Trustees of the American Medical Association who made this conference possible. They are highly appreciative of your generous response to the invitation and of your attendance at this conference of the altruism which prompted you to come here and participate in its proceedings and also for the high grade papers which were read and for the illuminating discussions which followed, and as you leave we will not say goodby but au revoir.

Dr. W. R. Redden, American National Red Cross, Washington, D. C.: I do not feel that this meeting has been at all one-sided. I think the visitors and the guests of the House of Delegates have greatly benefited by the conference. We therefore wish to express our appreciation to the House of Delegates for their invitation to the conference and for their hospitality during the meetings.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Personal.—Drs. John C. King, Pasadena, and Robert F. Rooney, Auburn, have been elected honorary members of the California Medical Association.——Dr. Raymond J. Strugel has been appointed health officer of Signal Hill ——Dr. Samuel B. Randall has been appointed health officer of Santa Cruz County to succeed Dr. Alfred L. Phillips.

Medical Golf Association.—There were ninety-eight members, including families and guests, in attendance at the tournament of the South California Medical Golf Association at Lake Arrowhead, June 25-26. Prizes were won by Drs. Earl W. Wells, Los Angeles, Charles Sidney Stevens, Santa Barbara, and John Vruwink, Walter R. Crane, William H. Kiger and Oliver W. Butler, Los Angeles. Prizes for the low net score for the year 1927 are to be presented in the form of two cups each about 40 inches high. There will be four other cups presented also, practically all of them on handicap, so that every member of the association has an equal chance to win, provided he plays in at least six tournaments during the year. This association will play the North California Medical Golf Association, September 24-25, in the northern area. There are now 175 members in the southern association.

COLORADO

Progress of School of Medicine.—During the three years that the University of Colorado School of Medicine has occupied its present location at Denver, the two hospitals have been filled to capacity and applications of students for admission to the school have exceeded the capacity. The class of fifty-six students entering last fall was selected from 119 applications, and 175 additional applications were received after the class was filled. The freshman class will be limited to seventy-five students. There is now a tax of one-tenth mill for the school of medicine, which puts the school on a sound financial basis, making it unnecessary to ask for support from the General Education Board, which, for three years, has contributed $50,000 annually toward running expenses. The millage tax also makes it possible to place the heads of all full-time departments on a twelve months basis instead of a nine months basis as at present. The clinics at the Colorado General Hospital and the Psychopathic Hospital are open at all times without charge to visiting physicians, and special courses for graduates are being outlined for the summer. Since the general hospital opened in December, 1924, a total of more than 6,000 patients has been admitted from fifty-seven of the sixty-three counties of the state. The school of medicine does not now make a special appeal for funds Its friends should know, however, that through special gifts or provisions in wills, medical research and education in the state can be encouraged. Endowments for student scholarships can be established with gifts of $3,600 each, endowments for research scholarships, with from $10,000 to $20,000 each; endowments for special clinics, with from $10,000 to $15,000 each, and an endowment for medical research, with from $100,000 to $200,000, the income to be used in aiding any department conducting promising original work

DISTRICT OF COLUMBIA

Two per Cent of Drivers Found Color Blind.—The introduction of a colored lighting system as a means of controlling the automobile traffic in the District of Columbia has disclosed that 2 per cent of the persons seeking permits to drive an automobile are color blind, and unable to distinguish the green from the red light Accordingly, the district traffic bureau has adopted the policy of refusing to grant permits to drive to such persons, as the colored lights serve only to confuse them and to increase the possibility of accidents.

FLORIDA

Hospital News.—The district hospital being constructed on Orange Avenue, Daytona Beach, is now under roof and will be ready for occupancy about January 1——The construction of the $150,000 Alachua County Hospital at Gainesville is under way

Society News. — Dr. William E Van Landingham was elected president of the Palm Beach Academy of Medicine, May 25; among the speakers at this meeting was Dr Bailey B Sory, Jr, Lake Worth, whose paper was on "Uterine Fibroids"——Dr Howard A Kelly, emeritus professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, addressed the Pinellas County Medical Society, recently, on emergencies in gynecology, Dr Kelly, who is spending his vacation in Orlando, has presented property to Orange County for a public park, according to the *Journal of the Florida Medical Association*——The Dade County Medical Society held a banquet, May 6, in honor of Dr. John A. Simmons; among others, Dr Walter C Jones, Jr, read a paper on "Pelvic Infections"

Chicago

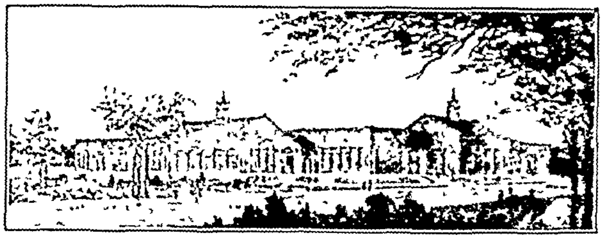
Thirty-Three Unlicensed Cultists Fined. — Thirty-three unlicensed cultists of Chicago were fined in Judge Hamlin's municipal court, July 8, on charges of practicing without a license Many of the cases had been pending since last October *The following chiropractors were fined $500 each:*

J E Teal, 2533 Milwaukee Avenue
Carl A Upson, 1105 East Sixty-Third Street
L E Pearson, 400 Irving Park Boulevard
Walter J Nowak, 4652 South Ashland Avenue
John Nowak, 1224 Milwaukee Avenue
Peter Sumaitis, 4652 South Ashland Avenue
A. M. Galbraith, 5814 West Chicago Avenue
Gertrude J Bogard, 3318 Lawrence Avenue
A J De Roeck, 3153 Lawrence Avenue
"Dr" William Karl, 4750 Broadway
Asa P Dyer, 4950 Milwaukee Avenue
Mrs Asa P Dyer, 4950 Milwaukee Avenue
Ira G Brown, 2501 North Kedzie Avenue
"Dr" Patrick J McCarthy, 2216 Jackson Boulevard

The following naprapaths received fines of $100 each:

Robert L Orrick, formerly 130 North Wells Street, has left the state
F A Manelis, 6117 South Talman Avenue
Louis A Rose, 501 South Crawford Avenue
J. Francis Doherty, 159 North State Street
A G Schlesinger, 159 North State Street
H A Riley, 159 North State Street
C E Kerrick, 159 North State Street
Lenore Yates, 159 North State Street
Lester Gill, 159 North State Street
Olive Harvey, 159 North State Street
Jennie Bowman, 162 North State Street
Helen Woodgate, 108 North State Street
William Stelling, 108 North State Street
Wallace Severance, 108 North State Street
A G Yancey, 108 North State Street
James E Taylor, 7912 South Halsted Street
Ira C. Atherton, 4554 Broadway
Albert Murry, 5206 West Chicago Avenue
Charles L. Lamon, 360 North Laramie Avenue

New School for Crippled Children.—The latest addition to the schools for crippled children of Chicago is the Walter S. Christopher School for Crippled Children which was opened, January 17. It occupies the entire block between Fiftieth and Fifty-First streets and Artesian and Campbell avenues, and was erected at a cost of $492,000. The building is designed especially for the care of crippled children; it is one story high, of modified Spanish architecture, and has a court with spacious lawns and playgrounds, eight porches, ramps for those who use wheel chairs, and provisions for 500 pupils. The board of education arranges for the transportation of the crippled children to hospitals, clinics and to the parks and other places of amusement, and provides them without charge with the midday meal. The principal of the school, Anna Henry, states that the physical care and corrective treatment of these children takes first place in the school's program. Parents are requested to give permission when a child enters the school for him to be taken to any necessary hospital, clinic or physician for examination or treatment. If the child is not already under the care of a private physician, he is taken promptly to an orthopedic surgeon for examination, and tuberculous cases are taken to the Municipal Tuberculosis Sanitarium dispensaries for examination. Regular school physicians call at the school to give routine examinations and to prevent outbreaks of contagious disease. The Chicago Heart Association sends a physician a half day a week to supervise the cardiac cases, while the corrective therapy recommended is carried out by the staff at the school, comprising three physical therapists, appointed by the board of education, a nurse furnished by the Visiting Nurse Association, and another furnished by the Municipal Tuberculosis Sanitarium. There is a special speech teacher who works one day a week with children who have speech difficulties, and a teacher is assigned to visit the homes of the children to secure the cooperation of parents. Necessary operations are arranged for through the social service departments of the hospitals, and the best orthopedic surgeons give their services in the needy cases. Wheel chairs, crutches, braces and so forth are either given free or on easy payments through private funds. The educational program emphasizes occupational therapy and vocational training fitted to the peculiar handicap of the pupil. There is an assembly hall where the children drill and play and thus develop muscle control. In addition to the Walter S. Christopher School for Crippled Children, Chicago has the Spalding School on Maple Avenue, west of Ashland Boulevard and adjacent to the Home for Destitute Crippled Children, and rooms set aside in two other schools for the care of crippled children.



IOWA

Appointments at Iowa.—Dr. Dorothy S. Dimond, formerly assistant anesthetist, has been appointed chief of the anesthesia department of the State University of Iowa College of Medicine, Iowa City, effective, July 1. Dr. Dimond is a graduate of the University of Minnesota Medical School, Minneapolis, 1922. Dr. Homer W. Scott, Fort Dodge, has been appointed assistant professor in the department of surgery. Dr Scott graduated at the state medical college in 1919, and was formerly connected with the department of surgery for about three years

Keokuk Alumni Meeting.—The alumni of the three medical colleges, formerly located at Keokuk, held a joint meeting, June 9, which was attended by 244 out of the 907 living alumni of these schools whose addresses are known. In addition there were in attendance many families, making a total of more than 700 who were entertained by the physicians of Keokuk at the country club. It has been nineteen years since the last class graduated and the college merged with the State University of Iowa Medical Department. Officers were elected and another meeting will be held in June, 1928

LOUISIANA

Personal.—Dr. E. W. Alton Ochsner has been appointed senior surgeon to the Charity Hospital, New Orleans, succeeding in that position Dr. Rudolph Matas.——Drs. Daniel R. McIntyre and Dorf Bean, Shreveport, have been appointed local medical examiners for airplane pilots by the U. S. Department of Commerce.——Dr. Henry W. E. Walther has resigned as editor of the *New Orleans Medical and Surgical Journal.*

Full-Time Organization in Surgery at Tulane.—The president of Tulane University announced at the ninety-third annual commencement, June 8, that the General Education Board has appropriated $150,000 to inaugurate a full-time organization in surgery in addition to the annual appropriation of the board of about $35,000 for the school of medicine. Other donations announced were an anonymous gift of $7,500 for the department of medicine and another anonymous gift of $9,750 and $15,000 from the General Education Board for the current expenses of the medical school.

The Fifes Were Pardoned.—The state pardon board granted a pardon, June 15, to chiropractors Joseph B. and Walter W. Fife, New Orleans, who were convicted a few years ago of practicing without a license, sentenced to thirty days in jail and the payment of a fine. The case was appealed until it reached the supreme court of the United States, and in each instance the decision of the lower court was sustained. The lieutenant governor of the state expressed his belief that the Fifes should be freed, the trial judge agreed to remit the sentence and the attorney general consented to the pardon. A petition with several thousand signatures was presented also. (THE JOURNAL, July 5, 1924; Nov. 1, 1924; Dec. 18, 1926.)

Hospital News.—The Baptist Hospital, Alexandria, is conducting a campaign for $100,000 to increase the bed capacity from 60 to 100, and to construct a new nurses' home.——Mercy Hospital, New Orleans, dedicated a new $250,000 wing, May 24, giving the hospital an addition of forty-one private rooms and six small wards, making the total capacity 117 beds. Mercy Hospital, which was first opened in 1924, was made possible by the gift of the buildings and grounds and an endowment of $160,000 by Mrs. Leonce M. Soniat.——The recent "strawberry week" for the benefit of the Charity Hospital, New Orleans, totaled about $3,150; it is expected that the drive "give a crate week" will become an annual event as a result of the success of the first venture.

MAINE

Rural Hospital for Farmington.—The Commonwealth Fund, New York, announces that the third of its series of rural hospitals will be erected at Farmington, Maine, a town of about 3,200 people, in a valley extending about 70 miles south of the Canadian border in the Rangeley Lake region. As with the other rural hospitals of the Commonwealth Fund, the local community will contribute about one third of the cost of the hospital and will assume the operating expenses. The fund will provide about $140,000 toward the cost of the construction of the fifty bed hospital, which will serve a wide range of surrounding country. About fourteen communities in eight states formally applied for the opportunity to build a hospital in connection with the fund. Farmington was chosen after a thorough study of the local needs and resources of each of these communities. Last year, similar arrangements were made by the Commonwealth Fund to build hospitals at Glasgow, Ky., and Farmville, Va.

MASSACHUSETTS

Personal.—Dr. George T. O'Donnell, Boston, has been appointed director of the tuberculosis division of the Boston City Health Department.——Dr. Henry P. Walcott, Cambridge, received the honorary degree of doctor of laws from Harvard University at the commencement, June 23.

Harvard Alumni Meeting.—About 100 alumni of the Medical School of Harvard University attended the annual meeting of the association at the school, June 22; the president, Dr. Philemon E. Truesdale, Fall River, presided. Among the speakers were Drs. Elliott C. Cutler, professor of surgery at Western Reserve University School of Medicine, Cleveland, and Elliott P. Joslin.

Orange Chiropractors Fined.—Glenton Thompson, a chiropractor of Orange, was found guilty in court, June 3, of practicing medicine without a license and was fined $300; he appealed. Hayden W. Allen, a chiropractor, was found guilty in the court at Orange, June 10, of practicing medicine without a license and fined $500; he appealed. Both these men are said to be graduates of the Palmer School of Chiropractic, Davenport, Iowa.

Dr. Arnold Appointed to State Board.—Governor Fuller appointed Dr. Horace D. Arnold, Boston, a member of the state board of registration in medicine, June 22, to succeed the late Dr. Charles E. Prior. Dr. Arnold, a graduate of the Medical School of Harvard University, was for several years a member of the House of Delegates of the American Medical Association, and later a member of the Council on Medical Education and Hospitals. He is a veteran of the World War, and was one of the original members of the National Board of Medical Examiners. For many years he was a teacher at the Harvard University and Tufts College medical schools.

Memorial Infirmary.—The Massachusetts Institute of Technology, Boston, is to erect a $150,000 infirmary to be named in honor of Richard Homberg, whose parents have made a gift of $100,000. The building will be four stories, forming a wing from the present main building near the Massachusetts Avenue side. The present infirmary will remain as the entrance to the new infirmary building. There will be two wards of five beds and four private rooms on the second floor; an isolation ward, operating room, kitchen, sterilizing room and a solarium on the fourth floor, and examination rooms, dressing rooms and offices on the first floor. Dr. George W. Morse, Jr., is the medical director and head of the department of hygiene at the institute; Dr. Louis W. Croke, assistant medical director, and Dr. Benjamin E. Sibley, assistant in the department.

MINNESOTA

Personal.—Major Roger Brooke, Jr., Medical Corps, U. S. Army, is spending three months at the Mayo Foundation, Rochester.

State Medical Election.—At the annual meeting of the Minnesota State Medical Association, Duluth, June 30-July 2, Dr. Charles B. Wright, Minneapolis, was elected president; Drs. Charles Bolsta, Ortonville, and Adolph G. Liedloff, Mankato, vice presidents; Dr. Earle R. Hare, Minneapolis, treasurer, and Dr. Edward A. Meyerding, St. Paul, secretary. The newly elected delegate to the American Medical Association is Dr. Jennings C. Litzenberg, Minneapolis, and the alternate, Dr. William F. Braasch, Rochester.

Hospital News.—The Webber Hospital, Duluth, erected at a cost of $200,000, was expected to be ready for occupancy in April.——A meeting was held at Rochester, June 28, to consider the need for a tuberculosis sanatorium in south central and eastern Minnesota. The entire boards of the county commissioners of Houston, Fillmore, Mower, Freeborn and Olmsted counties were present, and Steele County was represented by two members; many other interested persons attended the meeting. The facilities of the Mayo Clinic were tendered for the use of the district for this purpose. Another meeting was called for July 6 at Austin of all county commissioners of the counties mentioned, as well as others interested, to consider the question of making a tax levy to build a sanatorium for this district.

Annual Registration of Physicians Required.—All persons who were lawfully authorized to practice healing in Minnesota at the time that the Basic Science Act became effective will be granted a certificate without examination from the State Board of Examiners in the Basic Sciences, provided they apply to the secretary of the board for a certificate on or before Oct. 1, 1927, and present satisfactory evidence of having been lawfully authorized to practice healing before the act became effective. Such lawfully authorized persons who fail to apply for a certificate prior to October 1, may, at the discretion of the board, after paying a fee of $25, be issued a certificate of registration in the basic sciences at a later date. Another provision of the medical practice laws of Minnesota requires every person authorized to practice healing, and not excepted from the act, to register in January of each year with the secretary of the board of examiners which licensed him to practice, sending to the secretary his name and office address, and paying a fee of $5 for the years 1928 and 1929, and thereafter each year a fee of $2. The secretary will then issue a certificate for the current year which the registrant will display in a conspicuous place in his office. The present organization of the Minnesota State Board of Medical Examiners is as follows: Dr. Leon A. Barney, Duluth, president; Dr. Charles L. Sherman, Luverne, vice president; Dr. Alfred E. Comstock, St. Paul, secretary-treasurer, and Drs. Edward T. Sanderson, Minnesota, George B. Weiser, New Ulm, Charles E. Caine, Morris, and Julian F. DuBois, Sauk Centre, members.

NEBRASKA

Veteran Physicians Honored.—The Richardson County Medical Society gave a dinner, May 4, in honor of two veteran members, each of whom has been in the practice of medicine fifty-one years: Dr. John A. Waggener, Humboldt, and Dr. John C. Shepherd, Rulo. Dr. Waggener has three sons who are physicians, and Dr. Shepherd has one son who is a physician and is now president of the Richardson County Medical Society.

Society News.—Dr. Gladys R. Henry Dick, Chicago, recently addressed the Phi Beta Phi banquet at Lincoln, and also the staff of the Lincoln General Hospital at a dinner. ——Dr. Harry Benson, Oakland, was recently elected president of the Nebraska Academy of Ophthalmology and Oto-Laryngology at the fourteenth annual meeting in Lincoln. ——Two hundred and forty-seven premedical students from various schools in Nebraska were guests of the University of Nebraska College of Medicine in May at its annual premedical exercises.

NEW JERSEY

Medical Director Appointed.—Dr. Edward M. Z. Hawkes was appointed medical director of the Presbyterian Hospital at Newark, June 16, to succeed Dr. Samuel E. Robertson, who resigned after fifteen years' service and was made medical director emeritus.

Hospital News.—Edward T. Bedford has made a gift of a new unit to the Norwalk General Hospital, Norwalk, Conn., to cost not more than $500,000. Mr. Bedford is president of the hospital association, and chairman of the board of the Corn Products Refining Company.

State Medical Election.—At the annual meeting of the Medical Society of New Jersey, Atlantic City, June 9-11, Dr. Walt P. Conaway, Atlantic City, was elected president; Drs. Ephriam R. Mulford, Burlington; Andrew F. McBride, Paterson, and George N. J. Sommer, Trenton, vice presidents; Dr. Elias J. Marsh, Paterson, treasurer; Dr. John B. Morrison, Newark, recording secretary; Dr. William J. Carrington, Atlantic City, corresponding secretary, and Dr. Henry O. Reik, Atlantic City, editor of the journal and executive secretary.

NEW YORK

Health at Yonkers.—Telegraphic reports to the U. S. Department of Commerce from sixty-eight cities with a population of about 30 million, for the week ending July 2, indicate that the lowest mortality rate (5.7) was for Yonkers and that the rate for the group of cities as a whole was 11.7. The mortality rate for Yonkers for the corresponding week last year was 7.2 and for the group of cities, 11.7.

District Society News.—At a meeting of the executive committee of the First District Branch, Cornell Club, New York, June 7, it was decided to hold the next annual meeting, October 20, in the Bronx.——The executive committee of the Second District Branch, met, June 7, at the Shinnecook Hills Golf Club, Southampton, and decided to hold the next annual meeting of the branch in Jamaica in October in a hall "near the railroad station." It was also agreed to invite several leading scientists to read papers.——The executive committee of the Third District Branch met at the University Club, Albany, June 1, and decided to hold the next annual meeting of the branch, October 1, at Troy; the program will consist of a series of clinics at the local hospitals, followed by a luncheon at the new Hendrick Hudson Hotel, and scientific papers.——The executive committee of the Fourth District Branch met at Glens Falls, June 9, and decided to hold the next annual meeting at Schenectady, October 11-12; the program will include a series of clinics at local hospitals and at the General Electric Company plant in the afternoon of the first day, and a banquet and scientific papers the next forenoon; it was also agreed that a discussion of postgraduate courses and periodic physical examinations, among other topics, should be included on the program.——The executive committee of the Fifth District Branch met at Syracuse, June 2, and decided to hold the next annual meeting of the branch at Syracuse, October 13, the Onondaga County Medical Society acting as hosts. Among other subjects suggested for the program were "Postgraduate Education" and "Public Relations."——The executive committee of the Sixth District Branch met at Ithaca, May 25, and decided to hold the next annual meeting of the branch, September 27, probably at Johnson City, the Broome County Medical Society acting as hosts. It was decided to include on the program demonstrations of periodic health examinations and of the medical work of the Endicott-Johnson Shoe Company, and to invite two outstanding men in medicine and surgery to read papers. ——The executive committee and presidents of the component county medical societies of the Seventh District Branch met at Geneva, May 24, and decided to hold the next annual meeting of the branch, September 29, either at Geneva or at Clifton Springs, to invite several prominent men to read papers and to have a widely known speaker discuss period health examination methods and demonstrate the manner of making and reporting the examinations.——The executive committee of the Eighth District Branch and some of the presidents of the component county medical societies met at the University Alumni Club, Buffalo, May 26, and decided that the next annual meeting of the branch should be at Glen Ayr, October 6. It was suggested that Drs. William S. Thayer, Baltimore, President-Elect of the American Medical Association, Charles Gordon Heyd, New York, and Charles W. G. Crampton, New York, be invited to read papers.

Report on Relation of Physicians and Health Agencies.—The joint committee appointed by the Medical Society of the State of New York and the State Charities' Aid Association to study working relationships between the medical profession and voluntary health agencies has made a report. The committee has held several meetings since January, each of which occupied the better part of a day. The report was unanimously adopted by the house of delegates of the state medical society, May 29, and has been approved by the board of managers of the State Charities' Aid Association. It is not submitted as a final solution of the questions involved, but is regarded as a document with which medical organizations and voluntary health agencies at present may work in full accord. The joint report recommends that county medical societies include the following in their programs:

(*a*) Accept the invitation from the voluntary health agency to designate certain of its members to serve as members ex officio on the board of directors or executive committee of the voluntary health agency.

(*b*) Study and consider any program of activities that may be referred to it by the voluntary health agency for information and suggestions; and, if such program is approved, make a public statement to that effect, and otherwise support the program so approved.

(*c*) Appoint a special committee on public relations to confer from time to time with similar committees appointed by the voluntary health agency on matters of mutual interest to both agencies.

(*d*) Report to the state medical society any matter as to which an accord has not been reached with the voluntary health agency, in the hope that through conference between the state medical society and the parent body of the voluntary health agency any such matter may be negotiated and adjusted to the mutual satisfaction of all concerned.

The report recommends with regard to the voluntary agencies that they include the following in their program:

(*a*) Invite the county medical society to designate a certain number of its members, say two, to become members ex officio of its board of directors or executive committees, if there be one.

(*b*) Lay its annual program of activities before the county medical society for information and suggestions.

(*c*) Appoint a special committee to confer with a similar special committee appointed by the county medical society about matters that come up from time to time in which both groups are mutually interested.

(*d*) Report to the parent body of the voluntary health agency any matter as to which an accord has not been reached with the county medical society, in the hope that through conference between the parent body of the voluntary health agency and the state medical society any such matter may be negotiated and adjusted to the mutual satisfaction of all concerned.

(*e*) Conduct at least one open meeting each year to which the members of the county medical society are specially invited.

The state medical society was represented on the joint medical committee by Dr. George W. Cottis, Jamestown, chairman; Dr. Wilber G. Fish, Ithaca; Dr. William Warren Britt, Tonawanda; Dr. Thomas P. Farmer, Syracuse; Dr. Terry N. Townsend, New York, with Dr. George M. Fisher, then president, and Dr. Joseph S. Lawrence, executive officer, as members ex officio. The State Charities' Aid Association was represented by Dr. Livingston Farrand, Ithaca, chairman; Homer Folks, Yonkers; John A. Kingsbury, Yonkers; Dr. Herman G. Weiskotten, Syracuse, and Dr. Linsly R. Williams, New York, with George F. Canfield, president, and George J. Nelbach, executive secretary of the state committee on tuberculosis and public health, as members ex officio.

New York City

Hospital News.—A fund is being solicited to build and endow the Gotham Hospital of East Fifty-Sixth Street. Three million dollars is needed for endowment, so that the charges for patients of small income may be kept low. The staff will be composed entirely of women physicians; nurses, the *New York Medical Week* states, will be on an annual salary of $1,800. Each patient will have a separate room, and there will be no free treatment.

Personal.—Dr. Richard Kovacs is the director of the new department of physical therapy at the New York Polyclinic Medical School and Hospital. The department will serve for postgraduate teaching of physicians and nurses, and for clinical work in connection with a general hospital.——Dr. William W. Blackman recently received a "gold diploma" to commemorate the completion of his fiftieth year in the practice of medicine.——Dr. Jacques S. Uhr has been appointed assistant in pediatrics at the Knickerbocker Hospital.

University News.—Ninety-six graduates of Columbia University College of Physicians and Surgeons received medical diplomas at the commencement, June 1. The Dr. William Perry Watson prize for notable work in gynecology and pediatrics was awarded to Walter F. Duggan, Monson, Mass., and the Harold Lee Meierhof Memorial prize for research in pathology was awarded to Sylvan E. Moolten, Rockville Center, New York.——The Long Island College Hospital presented diplomas to seventy-one graduates in medicine at the commencement, June 2.

Society News.—The Kings County Medical Society has been requested to prepare plans for a health center for Coney Island; a gift of $50,000 by Mr. Morris Goldberg is available for the establishment of a health center.——The Harlem Tuberculosis Institute of the New York Tuberculosis and Health Association is conducting its fifth annual postgraduate course for the negro physicians from June 15 to August 3 at the Tuberculosis Division, Bellevue Hospital. The lecturers include Drs. Iago Galdston, George G. Ornstein, Foster Murray, Grant Thorburn, James A. Miller, Edward P. Eglee and Catherine R. Kelley. The lectures will be illustrated with clinical material.

OKLAHOMA

Use of Title "M.D." Constitutes Practice of Medicine.—In the case of *Reeves* v. *State*, the Oklahoma Criminal Court of Appeals recently upheld the constitutionality of the state medical practice act. John T. Reeves of Carter County had been found guilty by a lower court of practicing medicine without a license, in that he unlawfully appended to his name the titles "Dr.," "M.D.," "Specialist." Reeves contended that the medical practice act in its entirety was unconstitutional. The appellate court disposed of this contention with the statement that the power of the legislature to enact reasonable regulations for the protection of the public health was well settled, citing several Oklahoma cases in which the constitutionality of the act had been upheld. Another contention put forward in behalf of Reeves was that section 12 of the act was unconstitutional because it declared the use of the titles "Dr." and "M.D." to be evidence of practicing medicine without also requiring evidence that the alleged violator had attempted to treat disease. The court remarked in this connection that no case had been brought to its attention to uphold this contention; that the section referred to appeared to be an expression of the legislative intent to broaden the definition of the phrase "practice of medicine," and that the right of a state so to determine and define what constitutes the practice of medicine was well settled. So long as the statutory definition incorporates acts which in any substantial sense means the practice of medicine the statute will be upheld, the court stated. In the opinion of the court, assuming to practice by affixing or prefixing appellations to the name in a medical sense is sufficient to constitute the offense. Reeves filed a motion for a rehearing in the case.

PENNSYLVANIA

Personal.—Dr. Edward H. Rynearson, Mercy Hospital, Pittsburgh, was awarded first prize in the case report contest of the Allegheny County Medical Society; his subject was "Peritonitis and Acute Toxic Neuritis."——Dr. L. C. Owen Han, Ningpoo, China, died, January 16, at his home. Dr. Han took a year of postgraduate work at the University of Pennsylvania School of Medicine, and was an intern at White Haven for a year.

Tri-State Conference of Medical Officers.—The sixth tri-state conference of officers of the medical societies of the states of New York, New Jersey and Pennsylvania was held at Scranton, June 18. These meetings are designed to afford an opportunity to discuss problems of common interest to these states. The subjects discussed were (1) "Educating the Public in Medical Matters" and (2) "The State-Wide Antidiphtheria Campaign": Dr. Frank C. Hammond, Philadelphia, presented the former and Dr. Joseph S. Lawrence, the latter. Many other officers of the societies took part in the discussion; the Medical Society of the State of Pennsylvania tendered the guests a luncheon.

Northwestern Pennsylvania Physicians' Outing.—About 125 physicians from six counties in northwestern Pennsylvania, accompanied by their families, met in Erie at a dinner, July 8, which is the annual occasion in that community when sociability is one of the most important parts of the program. The wives were entertained by a committee of ladies from the Erie County Medical Society. Dr. Allen A. Jones, University of Buffalo School of Medicine, gave a clinical review of several cases, and Dr. Arthur C. Morgan, Philadelphia, president-elect of the state medical society, discussed the previous address and spoke further on the subject of medical legislation. The officers of this society of northwestern Pennsylvania physicians for the ensuing year are Oliver H. Jackson, Meadville, president: Fred E. Ross, Erie, vice president, and Michael V. Ball, Warren, secretary.

Philadelphia

Society News.—The Philadelphia County Medical Society unveiled two tablets, June 8, each containing the names of 100 life members of the society. The address on this occasion was given by Dr. James M. Anders.——The Northern Medical Association of Philadelphia celebrated its eighty-first anniversary, May 16, on which occasion many prominent physicians of the city were guests of honor.

Professors of Obstetrics and Gynecology Appointed.—The trustees of the University of Pennsylvania have elected Dr. Charles C. Norris as professor of obstetrics and gynecology, and as director of the combined department. Dr. Norris graduated from the University of Pennsylvania School of Medicine in 1898, and for many years has been a teacher at the school. The trustees also elected Dr. Floyd E. Keene as William Goodell professor of gynecology, and Dr. Edmund B. Piper was appointed professor of obstetrics.

Hospital News.—Dr. Samuel J. Gittelson has been elected president of the medical board of Mount Sinai Hospital, and Dr. Henry B. Shmookler appointed medical director.——The American Stomach Hospital, 1809 Wallace, said to be the first in the country established exclusively for the study of diseases of the digestive tract, launched a drive, May 19, for $250,000 for new buildings and equipment.——Friends of the late Jules E. Mastbaum have raised $20,000 to endow a ward in Rush Hospital to be known as the "Jules E. Mastbaum Ward for Women."

Physicians' Wills.—The late Dr. John G. Clark, gynecologist at the University of Pennsylvania School of Medicine, provided in his will for a bequest of $50,000 to the gynecologic department of the university, and provided for the endowment of the department of gynecology at the university hospital. Dr. Clark further provided $5,000 for the medical school of the university to be known as the "Undergraduate Medical School Fund," $100 of the income to be devoted as an honorarium for an annual lecturer to address the undergraduate society and to be known as the "John G. Clark Lectureship." The late Dr. Edward E. Montgomery, professor of gynecology, Jefferson Medical College, provided in his will, among other things, that on the death of his wife, $5,000 should be paid to the aid association of the Philadelphia County Medical Society.

TEXAS

Personal.—Dr. Albert O. Singleton, professor of surgery, University of Texas School of Medicine, Galveston, has been elected by the board of regents to the chair of surgery which was formerly occupied by the late Dr. James E. Thompson.

Society News.—The North Texas Medical Association held its semiannual meeting at Paris, June 14-15, and will hold its next meeting in Fort Worth, December 6-7. Every one of the thirty-one physicians scheduled to present papers at the Paris meeting responded.——At the seventh annual meeting of the Texas Pediatric Society, El Paso, recently, Dr. Lucius D. Hill, Jr., San Antonio, was elected president, and Dr. Edwin G. Schwarz, Fort Worth, secretary-treasurer.——Dr. Ralph H. Homan, El Paso, won the state medical association's golf tournament during the annual meeting at El Paso. Out of this tournament the Texas State Medical Golfers' Association was formed, and Dr. Bramwell F. Stevens was elected president.

Excerpts from Trustees' Report.—The State Medical Association of Texas will soon move its headquarters to new offices in the Medical Arts Building in Fort Worth, where it has a ten year lease made through the cooperation of the Tarrant County Medical Society. New steel furniture has been purchased for the offices. Under the new arrangements the library will be made available to physicians throughout the state, an attainment which the board of trustees of the state association has striven for for several years. In its report to the house of delegates at the recent meeting in El Paso, it appears that the board spent $20,128.96 on the educational campaign during 1925-1926, and that $10,000 was set aside in the last budget for continuing this campaign. The board feels that the association should spend a considerable sum on securing the enforcement of the medical practice act. There is needed in Texas, it is said, a system of registration of practitioners of medicine; the board of medical examiners is without a paid executive and the only trace of practicing physicians is through the 250 counties of the state, with so many possibilities for evasion of the law as relates to registration that the effort to convict persons of practicing without sanction of the law is most difficult. It appears that there is little chance of the legislature appropriating funds for a paid secretary of the board of medical examiners and for an enforcement official in the field, and the trustees suggest that a small fee be charged physicians for registration, the money to be used to finance the board of medical examiners in its enforcement work. This would not involve any additional expense to physicians, provided the state medical association could be relieved of the $8,000 or $10,000 a year it is now spending for law enforcement and publicity.

VIRGINIA

Additional Gift to Medical College.—The president of the University of Virginia announced, June 13, that the General Education Board had given an additional gift of $156,000 to the medical school for the further development of surgery, internal medicine and public health and hygiene, to be available over a period of six years beginning next September. This sum is not included in the $800,000 gift by the General Education Board previously announced for the construction of new medical buildings. No new appointments to the faculty were announced at this time, but it is expected that teachers will be named this summer to succeed Dr. Stephen H. Watts, professor of surgery and gynecology, and Dr. Isaac A. Bigger, Jr., assistant professor of surgery, who have resigned.

Infant Mortality in White and Colored Races.—Commenting on the infant mortality figures for 1926, recently released by the U. S. Bureau of the Census, the Virginia State Board of Health says that when the rates are divided into white and colored for Richmond, the cause of the high rate is evident. The white infant mortality rate in Richmond, it appears, was only 76 per thousand births, while the colored rate was 164. Norfolk had a white infant mortality rate of 50.8 and a colored rate of 151.5, thus giving that city a standing of 90. The white rate in Petersburg was 102.3 and the colored rate, 182.5. The white infant mortality rate of Portsmouth was 60.4, and the colored rate 160, making the rate for the city 108.6. The city of Staunton, the most distinctly white city of the state, appears to be an exception in that the white infant death rate was reported as 136, and the colored rate 250. The comment is made that in this case the deaths are probably all reported while the births are not, and that the people of Staunton should see that the report of births is also complete so that it may not appear that "one of the choicest of our Virginia cities" is not such a questionable place in which to rear a family. Charlottesville had a white infant death rate of 51.9, and a colored rate of 76.9 lower than the state as a whole. The white state rate is 71.8, and the colored 110. Infant deaths may be reduced by prenatal care, and the state board of health furnishes a correspondence course which all prospective mothers may take.

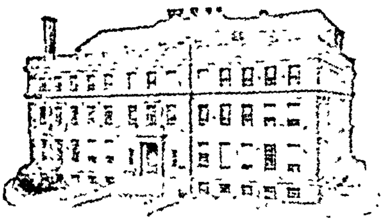
WEST VIRGINIA

Society News.—Dr. Dean Lewis, Baltimore, addressed the Ohio County Medical Society, Wheeling, recently, on "Diagnois of Bone Lesions," illustrated with lantern slides.——Dr. John B. Deaver, Philadelphia, addressed the Ohio County Medical Society, Wheeling, May 27, at the annual banquet; Dr. John W. Gilmore was elected president of the society for the ensuing year, and Dr. John G. Thoner was elected secretary for the third consecutive time.——Dr. Chester R. Ogden, Clarksburg, president of the state medical society, addressed the Barbour-Randolph-Tucker County Medical Society, Philippi, May 26; Dr. Ernest R. McIntosh read a paper on "Mental Healing"; the advisability of changing the name of the society to the "Tygarts Valley Medical Society" was considered but no definite action taken.——The Kanawha County Medical Society held a symposium on cancer, May 3; the speakers were Drs. John E. Cannaday, Robert K. Buford, Rome H. Walker and William A. Thornhill; Dr. Ray M. Bobbit, Huntington, addressed the society, May 31, on "Urinary Calculi," and Dr. Earl Bennette Henson, Charleston, on "Bone Sarcoma."——Dr. and Mrs. Garnett P. Morison, Shepherdstown, entertained the Eastern Panhandle Medical Society, June 15; among others, Dr. Emmert C. Stuart, Winchester, Va., read a paper on "The Prostate from the General Practitioner's Viewpoint."

WYOMING

First State Tuberculosis Sanatorium Dedicated.—The pioneer tuberculosis sanatorium of Wyoming was opened to public service on National Hospital Day, May 12, with appropriate ceremonies conducted by state officials. The sanatorium is at Basin in the Big Horn Mountain country, and as yet comprises only one building of thirty beds which, it is expected, will be the nucleus of larger development. Dr. Stephen O. Watkins, Basin, is the superintendent.

CANADA



School of Hygiene Opened.—The new building for the School of Hygiene of the University of Toronto was opened, June 9. The *Canadian Medical Association Journal* states that the building is a gift of the International Health Board of the Rockefeller Foundation, New York, and was built under the direction of the department of health of Ontario and the University of Toronto. It is one of three which have been established in North America by the Rockefeller Foundation, the others being at Harvard University and Johns Hopkins University. The building will accommodate the department of hygiene and preventive medicine, the department of public health nursing of the university and the Connaught Laboratories. Dr. John G. Fitzgerald, professor of hygiene, and director of the Connaught Laboratories, will be director of the new school of hygiene. At the opening ceremonies, Sir George Newman, chief medical officer, department of health for England and Wales, gave an address on "Medicine as a Science to be Learned in Laboratory and Field."

GENERAL

Fellowships Provided by Rockefeller Foundation.—During 1926, the Rockefeller Foundation provided either directly or through other agencies fellowships for 889 persons from forty-eight countries; of these, 386 fellows crossed national boundaries to pursue their studies. During 1926, the foundation contributed to the budget of the National Committee for Mental Hygiene, including funds for fellowships for the training of personnel, and made gifts also to the Canadian National Committee for Mental Hygiene which, among others, is granting fellowships to advanced students.

Hospitals Approved and Removed from List for Training Interns.—Since the list of hospitals approved for internships was published in The Journal, March 12, 1927, the Council on Medical Education and Hospitals has approved the following additional hospitals for the training of interns:

Roseland Community Hospital, Chicago.
U. S. Marine Hospital number 1, Baltimore. Affiliated with University Hospital for training in obstetrics and pediatrics.
Eitel Hospital, Minneapolis.
U. S. Marine Hospital number 21, Staten Island, N. Y. Affiliated with the Staten Island Hospital for training in obstetrics, gynecology and pediatrics.
Flower Hospital, Toledo, Ohio.
Montgomery Hospital, Norristown, Pa.
St. Michael's Hospital, Toronto, Ontario.

The following hospitals have been removed from the list:

Columbus Hospital, Chicago, for failure to meet certain requirements regarding the training of interns.
Easton Hospital, Easton, Pa., for lack of balanced experience and training for interns, its work being mainly surgical.

The statement concerning the hospitals removed from the list does not imply a lack of competence in the care of their patients, and the lack of approval should not apply to interns secured prior to the publication of this notice.

Report of Board on Typhoid in Montreal.—The board of officers of the U. S. Public Health Service appointed to investigate, with the permission of the Canadian health officials, the Montreal typhoid epidemic has made a report to Surg. Gen. Hugh S. Cumming. The survey, which began June 18, and terminated June 29, included an examination of the typhoid records of the city and other parts of the province of Quebec; survey of the city water and sewage sources; an inspection of the milk plants and dairy farms in the surrounding country; a collection by personal interview of detailed histories of 203 cases, and a consideration of the adequacy of the local health force to cope with the situation. According to official records, there were reported between March 1 and June 28, 1927, 4,755 cases of typhoid in the city of Montreal with 453 deaths, as against thirty-seven cases and eleven deaths from March 1 to June 30, 1926. No evidence was obtained by the board to suggest that the water supply or sewerage system operated in the spread of the epidemic. The official records show that soon after the outbreak a large proportion of the patients gave a history of drinking milk from the plant of the Montreal Dairy Company, Ltd.; there was no evidence found of any significant disproportion of cases among habitual users of milk from the other dairy plants. About 32 per cent of the cases were reported among children under 10 years of age. It was concluded that the vast bulk of the infection causing the epidemic of typhoid was disseminated in the milk distributed by the Montreal Dairy Company, although exactly how the infection was introduced into this local supply has not been determined. The report of the board indicates that the cause of the epidemic began operating about February 15, reached its maximum about March 5, continued high until March 18 and then declined rapidly; in fact, it is probable that there was a complete cessation of the main current of infection from March 27 to April 20, when there was another sharp rise in the rate of causation, which began a rapid decline about May 6. The cases reported with onsets subsequent to May 25 have been in decreasing proportion among persons exposed to the milk of the Montreal Dairy Company and in increasing proportion among persons exposed to previous cases.

In the farming communities from which milk was obtained by the Montreal Dairy Company, surface streams were commonly used as sources of water for the milk houses and for the disposal of sewage from homes upstream. In conveying the milk from the farms to the city plant, there was a possibility of introducing typhoid infection at the receiving stations, at one of which the water used mainly for washing the cooling vats and other equipment was pumped from a river. It appears from the charts at the city plant that such milk as was run through the pasteurizer was, with occasional minor exceptions, heated sufficiently to kill all typhoid bacilli. The question is, the board states, where and how the infection could have been introduced in sufficient volume to account for the epidemic. The general epidemiologic evidence supports the view that the main current of infection was probably in the raw milk as it entered the plant and that through advertence or inadvertence on the part of workers in the plant, a considerable proportion of the raw milk was distributed from the plant without sufficient pasteurization, or even a run through the pasteurizer during the periods from February 15 to March 27, and from April 20 to May 15. It is true that in a foreman of the plant of the Montreal Dairy Company, a positive Widal blood reaction was obtained, April 6; the urine was found repeatedly negative and the feces were positive in four out of nine examinations. He had worked for about seven years at the creamery of the company before going to work at the milk plant, February 5, which date synchronizes with the beginning of the causation of the epidemic. It was difficult for the board to conceive why, if he started the current of infection, he ceased to infect the milk during the period from about March 6 to the date on which he was removed from the plant, April 16, and it appears unreasonable to suspect that he was a causative factor in the recrudescence of the epidemic.

The board believes that the city health officer recognized his responsibility and did his best to render efficient service under most difficult circumstances. That he should be given adequate efficient personnel at once to cope with the present situation is considered of critical importance to the city. The number of new cases of typhoid reported for the ten days ending June 28 averaged more than ten a day. The report states that Montreal is not yet a comparatively safe city for visitors who are likely to be susceptible to typhoid infection. The board acknowledges the many courtesies and the assistance received from the health agencies of the dominion, the province and the city, as well as from other agencies and many individual citizens.

FOREIGN

Postgraduate Course in Balneology.—The ninth Karlsbad international postgraduate course in balneology and balneotherapy will be held, September 18-24. The course is open to all medical practitioners, for whom full opportunities for studying the local therapeutic institutions will be provided. In connection with the course a Czechoslovakian visa will be supplied without charge and a 33 per cent reduction allowed on the state railways. Further information may be obtained from the secretary, Dr. Edgar Ganz, Karlsbad.

American Fellowships for Honor Graduates.—Twenty-three honor graduates of British universities were awarded fellowships by the Commonwealth Fund, New York, it was announced May 20, and they will come to the United States next fall for two years' study at various universities. The fellowships amount to $125,000, and this is the third annual group of such awards, twenty being provided annually under the original plan. This year, three new fellowships for honor graduates of British colonial universities were added. The awards were made by a committee of educators, and 121 applications were received. The study is not to be limited to any particular field; fellows are required to travel widely in the United States, attending meetings of learned societies, and thus come in contact with eminent men in their field. Among others, James M. Alston, from the University of Edinburgh, will come to Harvard University, Boston, and Thomas F. Hewer, from the University of Bristol, to Johns Hopkins University to study bacteriology.

Honorary Degrees and Society News.—The University of Edinburgh will confer the honorary degree of LL.D. on the occasion of the annual meeting of the British Medical Association in July on Dr. William S. Thayer, Baltimore, President-Elect of the American Medical Association; Dr. Harvey Cushing, Moseley professor of surgery, Medical School of Harvard University, Boston, and Dr. Charles L. Dana, professor of clinical medicine, Cornell University Medical College. Dr. Cushing delivered the annual oration before the Medical Society of London, June 13, on the surgical aspects of acromegaly.——The *Kenya Medical Journal* has been formally recognized by the Ranganyika Branch of the British Medical Association, and has changed its name to the *Kenya and East African Medical Journal*.——The subject for the Jacksonian prize of the Royal College of Surgeons of England for 1927 is "The Pathology, Diagnosis and Treatment of Bronchiectasis and Abscess of the Lung," and the competing essays must reach the secretary not later than December 31. The subject for 1928 is "The Surgical Treatment of Pulmonary Tuberculosis."——Lord Riddell was host to the Medical Golf Society of London during the annual meeting, June 16, at Walton Heath; there were more than 100 entries and about eight prizes were awarded.

Disciplinary Action by British Council.—At the May 24 meeting of the General Medical Council of the British Medical Association in London, a number of disciplinary cases were considered. No name was erased from the register for misconduct, the *British Medical Journal* notes, but in six cases judgment was postponed until a later session of the council. These cases included one concerned with advertising, one with lax certification, three with convictions for drunkenness, and three in which practitioners in Scotland had been keeping a "medical hall" where scheduled poisons had been sold to the public by an assistant not legally qualified, who, it was alleged, had been acting under cover of the physician. The case of advertising concerned a member in India registered in the army medical service. He had practiced for a long time in India and, it appears, had an honorable career. Newspaper notices promoting his qualifications were inserted more or less by acquaintances in a friendly fashion following his return to India from England. He had attempted to determine through the local medical council in India whether ethical medical regulations had been contravened. The General Medical Council took a serious view of the offense, as was proved at the hearing, and postponed judgment until May, 1928.

Deaths in Other Countries

A. H. Freeland Barbour, formerly president of the Royal College of Physicians of Edinburgh, author of books on gynecologic subjects, June 11.——**Frederick Lange**, Berlin, Germany, formerly a practitioner in New York, and founder of the Lexington Hospital, recently, aged 77.

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 25, 1927

The Royal Society Exhibition

At a conversazione given by the Royal Society, many exhibits of medical interest were shown Mr A A King showed the application of ultraviolet radiation from a mercury vapor lamp to the detection and estimation of minute quantities of arsenic When a mercury arsenic stain on a piece of filter paper sensitized with mercuric chloride is examined by means of ultraviolet rays the unchanged mercuric chloride fluoresces blue, while the mercury arsenic stains stand out as a black disk Arsenic stains, which are quite invisible in ordinary light, may be revealed in this way and it is said to be possible to detect and estimate quantitatively amounts of arsenic as small as 0 00001 mg Impurity in distilled water is also revealed by fluorescence in ultraviolet rays, and it has not yet been found possible, even with the most refined methods of distillation to prepare water that does not show some signs of fluorescence An exhibit from the National Physical Laboratory also illustrated the difficulty of preparing substances in a state of absolute purity It included specimens of iron, manganese and chromium, the impurities in which are detectable only with the spectroscope Bolometers responding with remarkable rapidity to radiant heat were shown by Mr H Dewhurst, they consist of a narrow strip of bismuth, believed to be only 0 0000007 cm thick, deposited on thin celluloid films by electrical evaporation

The Influenza Epidemic

The part played by influenza as an indirect cause of mortality may be seen from the fact that during the first quarter of the present year, when this malady was epidemic, the number of deaths in England and Wales exceeded the number of births by 1,644 In the first quarter of 1924, 1925 and 1926, when influenza was not epidemic, the increase of births over deaths numbered, respectively, 25,115, 37,224 and 43 477 The birth rate has now fallen so low that any serious outbreak of influenza is likely to reduce the population, not only relatively but absolutely The epidemic of the present year began apparently in London, where the highest point was reached in the last week in January The south of England followed quickly The highest point of the epidemic was not reached in the midland till the third week of February, the north of England, which was severely attacked, had its highest point at the end of February The influenza epidemic killed, in its short duration, 17,931 persons in England and Wales, the largest number of deaths from influenza in any first quarter since 1919, when the terrible pandemic occurred The birth rate in the first quarter was 17 3 per thousand, the lowest ever recorded except that of 1919 The death rate was 17 5 per thousand

Sleep and the Aged

The view that questions of diet and sleep are largely a personal matter, and that some people are able to attain a lusty old age while defying many of the accepted laws of health, was expounded with many examples within his own experience, by Sir Thomas Oliver, professor of medicine, University of Durham, in his presidential address to the Institute of Hygiene on the "Hygiene of the Later Period of Life" To loss of sleep were attributed some of the alterations which tend to anticipate old age But the personal element came in, and once when visiting a well known peer, who was then far advanced in the nineties and who died two years short of his century, Sir Thomas was asked by him, as he was a victim of insomnia, how many hours' sleep a man should have He replied six, but qualified that statement by the remark that many men went through life, discharging its duties satisfactorily, with only four. The peer replied, "You are quite right, for I have seldom had more than four hours' sleep in the twenty-four during the past fifty years" A few years ago Sir Thomas visited Edison in his works in New Jersey and learned from him that during the previous week he had sleep twenty-two and a half hours, less than the daily minimum of four hours to which he had referred, yet Mr Edison's powers were as good as ever He was actively engaged in research, and was conducting the affairs of a large laboratory Two and a half years ago he again visited Mr Edison, who resumed the conversation interrupted a few years previously, thus indicating that even prolonged loss of sleep had neither weakened his memory nor diminished his mental activity

Kala-Azar

The annual report of the School of Tropical Medicine devotes attention to the researches regarding the spread of kala-azar, "the one remaining unsolved problem of transmission of a great tropical disease" Kala-azar is a remittent fever of the malarial type, characterized by anemia and enlargement of the spleen and liver It is certain that the silver-footed sandfly can carry this disease, but the special conditions under which it is capable of infecting man have not yet been discovered The report maintains that the evidence as to the carrier is strong enough to encourage the hope that the elimination of the sandfly means the elimination of kala-azar

The Drugging of Panel Patients

The wasteful consumption of drugs by panel patients, owing to the complacency of physicians, has been pointed out heretofore A number in Scotland are certainly getting their "money's worth" One man to date has been prescribed 8 830 pills, and there is no indication of his giving up the treatment Another has received about 2½ hundredweight of ointment, while a third has been medically advised to drink 55 gallons of distilled water These facts were revealed in the records of the Scottish Central Checking Bureau for the National Health Insurance services

Roentgen-Ray Victim: Carnegie Hero Fund Grant

Dr G C W Williams, who did valuable roentgen-ray work from 1895 until last year, and served in the army through the war, has been made an allowance of $600 a year by the trustees of the Carnegie Hero Fund He contracted dermatitis as a result of his work, and after eight operations, which included amputation of his right hand and loss of two fingers of his left, he was obliged to give up all hope of a cure, and one by one his professional engagements had to be relinquished

Safety First in Factories

The home secretary, who at the recent annual meeting of the Safety First Association foreshadowed the possibility of the compulsory provision of safety officers in the larger factories, has now issued to the employers' associations a letter stating that he had provisionally approved the issue of an order requiring the institution of special safety arrangements in the chief accident-producing industries Progress in the development of safety first arrangements in factories he finds to be disappointingly slow The total number of accidents reported shows no sign of substantial reduction, and while a certain proportion were preventible by fencing and similar mechanical precautions which could be made the subject of specific regulation, the majority—perhaps in some cases as much as 60 per cent—were due to other causes The chief, if not the only, hope at present of effecting any substantial reduction in the total number of accidents seemed therefore to lie in a much closer and more comprehensive measure of supervision being exercised at the individual factories, which could be secured only through establishing at the works special safety organizations which would insure that the circumstances and causes of all the accidents occurring were closely investigated and the best methods of carrying on work with safety carefully studied; that the workers were instructed in the risks and imbued with safety first principles, and generally that all practicable means were taken for the promotion of safety methods. Before proceeding, however, to make the order, the home secretary desired to give employers' associations the opportunity to submit observations on the proposals, with a view to ascertaining whether the employers in any of the industries affected would not voluntarily take the necessary steps at their works. If he were assured that the employers in any of the industries concerned were ready to adopt effective safety schemes on the lines indicated in the order (or on such other lines as may be approved) and that effective steps would be taken without delay to institute such arrangements, he would be quite willing, so far as that industry was concerned, to postpone the issue of the order so as to give the employers the opportunity of dealing with the matter on a voluntary basis. It is proposed to require employment of a competent safety supervisor. The order, however, is elastic, and every occupier would have the opportunity of substituting, with the chief inspector's approval, a special safety scheme adapted to the particular circumstances of his works. He would also be able to claim exemption altogether from the order if he could satisfy the chief inspector that other not less effective measures for the prevention of accidents had been adopted. It is proposed that the order shall apply to (1) blast furnaces for the smelting of iron ore; (2) iron and steel rolling mills, including tube works; (3) engineering works in which more than 500 persons are employed, as follows: forges, engine building, making of transmission machinery, constructional engineering, hydraulic engineering, electrical engineering (making of dynamos and motors, and cable making), making of agricultural and industrial machinery, making of railway, street car and motor vehicle plant, ordnance works; (4) iron foundries in which more than fifty persons are employed; (5) shipbuilding works.

Registration of Nursing Homes

In the house of commons the second reading of the nursing homes (registration) bill was carried. Its principle has already been approved by a select committee of the house, which found that the premises of many nursing homes were structurally defective and unsuitable for the purpose to which they were devoted; the committee recognized the urgent need for registration and supervision, particularly in regard to homes which catered to poor people and senile chronic cases; and it considered that, in many nursing homes, the accommodation for the nursing staff was seriously defective. The committee recommended that the administration of registration should be carried out by the local authorities under the supervision of the ministry of health. The bill gives effect to these recommendations. It proposes that the local authority should have power to refuse registration on the ground that the applicant is not a fit person or that the premises were unsuitable. The person in charge and a proportion of the staff will have to be qualified nurses, but in the case of homes which existed at the time the bill took effect, it would not be a bar to registration if the person in charge was unqualified so long as the person who superintended the actual nursing of the patients was a qualified nurse.

PARIS

(From Our Regular Correspondent)

June 8, 1927.

The Water Supply of Paris

The problem of securing an adequate supply of drinking water for Paris is difficult, particularly for the suburbs, in which the population is increasing rapidly. Furthermore, the suburbs waste water in caring for their lawns and gardens. The projects being considered at present concern the harnessing of distant springs (for example, those of the Loir) and the use of water from the Seine, sterilized in special reservoirs, either by the admixture of sodium hypochlorite or by ozonization. The first plan will be rejected no doubt as being too expensive and because the inhabitants of the region of the Loir refuse to be deprived of their water. Also in case of war, destruction of aqueducts by the enemy or even poisoning of the water is possible. The second project is more economical. Many Parisians are, however, opposed to the use of water from the Seine on the ground that it has not an agreeable taste and would not be cool in summer. A third plan calls for a reservoir with an area of 2,844 hectares to be constructed in the department of the Aube. It would flood a whole valley. The method has been employed with success in the Pyrenees, but those mountain valleys were sparsely populated and the land had no practical value; furthermore, the quality of the water was of little importance. The reservoir in the Aube would destroy many acres of fertile fields, would constantly threaten with inundation the city of Troyes in case of a break in the retaining walls, and would supply a water the quality of which would not be superior to that of the Seine.

The Tragic Death of Prof. Robert Picqué

Dr. Robert Picqué, formerly a member of the army medical corps and likewise formerly agrégé professor in the Ecole supérieure du service de santé militaire, recently appointed professor of clinical surgery at the Faculté de médecine de Bordeaux, has just been killed. For several years, Picqué had devoted himself to furthering the transportation by airplane of injured persons. During the World War, he had promoted the establishment of surgical stations in dugouts close to the front-line trenches and under the fire of the enemy. Later, he organized medical service aviation during the campaigns in Morocco and Syria. The accident which caused his death occurred when he was informed of the serious condition of the wife of an officer in the aviation camp at Cazaux (Gironde). He went to her assistance in an airplane, accompanied by another plane for the transportation of the patient. On the return in squadron formation to Bordeaux, Professor Picqué's plane caught fire. Picqué, embarrassed by the smoke, left his seat and tried to make his way to the front of the cockpit where sat the pilot, who was making as rapid a descent as possible. But he must have made a false step, for he lost his balance and fell out of the plane, while the pilot made a safe landing and succeeded in escaping the peril of the flames. Professor Picqué was killed instantly. He was only 50 years of age.

Sunday Closing of Pharmacies

The unpopular ordinance requiring the closing of most pharmacies in Paris on Sundays gives rise to many comic and tragic incidents. Recently, a policeman who had, following instructions, compelled a pharmacy to close on a Sunday, came back, a few hours later, to seek the pharmacist's aid, as he had been injured in an accident and could not find a cab to take him to the hospital. The pharmacist was kind enough to comply with his request. At another pharmacy, which was closed in accordance with the ordinance, policemen endeavored to secure aid for a woman who had been injured on the streets, but the pharmacist refused to open his shop. However, in spite of the complaints of the public and the noisy demands of a few pharmacists, the majority of the pharmacists favor the continuance of the ordinance, whether from personal choice or (which is more likely) as the result of the pressure brought to bear by the union of pharmacy employees, who threaten to strike if the ordinance is repealed.

Opening of the First Hospital for the Insane in Algeria

A hospital for the insane has recently been officially dedicated at Blida, Algeria. It is the first hospital of the kind to be established in Algeria. The Mohammedans regard insane persons as inspired by Allah and treat them with veneration, giving them assistance whenever they encounter them. Such kind treatment and the absence of insanity resulting from alcoholism will explain why cases in which internment is necessary have been rare. But alcoholism is beginning to develop among workmen in the seaports and employees in factories, and hospitals for the insane are now needed. It is planned to erect further hospitals for the insane as soon as possible.

Social Insurance

The senate began this week the debate on the bill pertaining to social insurance. The bill was adopted in 1924 by the chamber of deputies without prolonged discussion. Since that time, the medical profession has expressed anxiety concerning the consequences that may result from the adoption of the bill. The government has postponed the consideration of the bill by the senate in view of these criticisms and because of the impossibility of making provisions for the new items with which the budget would be loaded. Also, the cost of living would increase because merchants and industrialists would add to the selling prices of their products a sufficient amount to cover the increased charges imposed on them by the new law. The debates in the senate are being followed with the greatest interest by all physicians.

The Use by a Surgeon of His Own Blood in Performing a Transfusion

Dr. Hertz, chief surgeon at the Rothschild Hospital, found one night that a preoperative transfusion of blood was indispensable in a case of ruptured extra-uterine pregnancy. He found that no one present had blood that was compatible with the blood of the patient. Only the blood of the surgeon was acceptable. Dr. Hertz supplied the patient with his own blood for the transfusion, after which he operated on the patient and succeeded in saving her.

The Nineteenth French Congress of Medicine

The nineteenth French Congress of Medicine, which will be held in Paris, October 11-14, under the chairmanship of Professor Teisier, has announced its program, which will consist of three topics as follows: (1) semeiology of medical septicemias, with papers by P. Gastinel and J. Reilly (of Paris) on general semeiology of the septicemic condition, M. de Vezeaux de Lavergne of Nancy on clinical forms of specific acute and chronic septicemia from a known or unknown virus, and by F. Arloing, P. Dufourt of Lyons and L. Langeron of Lille on clinical forms of nonspecific chronic or acute septicemia; (2) the pathologic physiology of edemas, with papers by E. Aubel and P. Mauriac of Bordeaux on the rôle of certain ions and on the variations in their distribution in the pathogenesis of edemas, P. Govaerts of Brussels on the rôle of the physicochemical properties of proteins in the pathogenesis of edemas, with researches on the variations of the osmotic and capillary pressure, and Pasteur-Vallery-Radot and P. Nicaud of Paris on edemas in chronic interstitial nephritis, and (3) the medical indications and the comparative therapeutic value of splenectomy, with papers by N. Fiessinger and P. L. Brodin of Paris on splenectomy in hemolytic processes, A. Nanta of Algiers and J. Tapie of Toulouse on splenectomy in anemic processes, A. Nanta on anemia of parasitic or infectious origin, and J. Tapie on pernicious and leukemic anemia. In order to give to the main topics as much time as possible, the program committee has decided not to accept any communication that does not bear directly on the main topics. In connection with the holding of the congress, the centenary of Villemin and his discovery of the value of inoculation in tuberculosis will be celebrated.

ITALY

(From Our Regular Correspondent)

April 15, 1927.

Experiments with Bread Containing Soy Bean Flour

At the order of the minister of war, a commission composed of physicians and chemists attached to the army service and presided over by Professor Memmo, member of the army medical corps, with the rank of general, has completed alimentation tests with bread containing 10 per cent soy bean flour. The experimental subjects were army officials (physicians and pharmacists) and soldiers of the regular army, who volunteered their services. The specimens of flour used for the test were furnished gratuitously by two Italian wholesale houses, and had been milled by different processes. The tests were conducted over a period of several weeks, and the commission recently presented to the minister of war its conclusions, which were most favorable to the adoption by the army of bread containing a percentage of soy bean flour.

Provisions for the Benefit of Pregnant Prisoners

In a recent circular addressed to the procurators of the appellate courts, the minister of justice, Professor Rocco, calls attention to the fact that often pregnant women are interned in penal institutions and give birth to children under very unfavorable surroundings. With a view to protecting the rights of motherhood and childhood, the minister decrees that, in case a pregnant woman, or a woman who has given birth to a child within three months, receives a jail or a prison sentence, execution of the sentence shall be suspended. Similar provisions are contained in the Italian Codex under the head of penal procedure, but, up to the present time, have not been applied to as wide an extent as the minister desires.

The Marchiafava Foundation

The prize of the Marchiafava Foundation for the best work on pathologic anatomy and experimental pathology (8,000 liras, or $368) has been awarded to Professor Soli, occupant of the chair of pathologic anatomy in the University of Palermo, for his researches on experimental arteriosclerosis from *Spiroptera sanguinolenta*, and to Professor Brancati, of the Clinica Chirurgica in Rome, for his investigations on internal experimental tar cancer.

Report on Sanitary Conditions in Italy

The public health service, which is under the ministry of the interior, has recently published a report on the sanitary condition of the country from July 1, 1925, to June 30, 1926, from which it appears that public health conditions remained normal during the period covered by the report. The general mortality rate was 16.58 per thousand of population, as compared with 16.61 for the preceding twelve months. The birth rate was 27.46 per thousand of population, which constituted a decline over the birth rate for 1924 (30 per thousand). The percentage of children to the total population is in Italy very high—higher than in most other countries. Especially noteworthy is the decrease in the number of deaths among children under 1 year of age. Exotic diseases did not present any conspicuous manifestations. Of the exanthematous diseases, there was evidence of a still further decrease in scarlet fever, while measles showed an increase. The manifestations of smallpox were few and very light. The public health service gives careful attention to the prophylaxis of smallpox, and is organizing more and more effectively the vaccination service. With regard to tuberculosis, while the mortality figures as a whole, taking into consideration all the various forms of the disease, have gradually dropped to about the prewar status, the mortality for the pulmonary forms remains high. More intensive prophylaxis is therefore needed, either through the mediation of the provincial antituberculosis societies, or through the activities of the institutions for the assistance of weak and predisposed children. Malaria continues to decrease. In the anticancer crusade, the public health service has made its contribution through the creation of the physical laboratory and the radiologic bureau, the purpose of which is to deal with all subjects pertaining to physics and radiotherapy. It has likewise established at Rome a special hospital (S. Gallicano) to serve as a study center for the practical application of physical therapy to tumors, and has placed in the budget an annual appropriation of two million liras ($92,000) for the prosecution of studies on cancer. During the fiscal year 1925-1926, the number of free antitrachoma dispensaries was increased from 156 to 196. A special inquiry has been begun to determine the present incidence of trachoma. Pellagra has almost completely disappeared from Italy. For the completion of sanitary undertakings there were authorized in 1925-1926 accommodation loans totaling 162,000,000 liras ($7,452,000), 140,000,000 ($6,440,000) of which was used for the construction of water works, and 22,000,000 ($1,012,000) for sewerage systems, cemeteries and the like.

The "Policlinical Hour" as Established in Padua

The Poliambulanza Medico-chirurgica of Padua, at the suggestion of Prof. Gaetano Boschi, has introduced recently an innovation among the medical assistants of the ambulatorium by establishing the so-called policlinical hour, in accordance with which fourteen medical specialists connected with the institute meet every week, at a given time and place, to determine what cases, though belonging apparently to a single specialty, present in reality syndromes of a complex nature that demand the intervention of various specialists. Thus, an attending physician, confronted with a difficult case, can take his patient for a consultation at the meeting of the group of specialists.

Convention of the League for Combating Cancer

The Lega italiana per la lotta contro il cancro, of which Professor Lustig is the chairman, has called a meeting in Milan of all those who are actively interested in the crusade against malignant tumors. Not only physicians but also administrators of hospitals, directors of charitable societies, students of social questions, and the like, are invited to attend the convention. The objects of the meeting are to make known what the league has done and what it is planning to do in the way of defense against cancer, to solve certain practical problems, and to afford an opportunity for an exchange of ideas and of programs on the part of the persons attending.

Government Aid in the Crusade Against Tuberculosis and Cancer

The minister of the interior has decided to make each year special grants for the promotion of work in tuberculosis and cancer, from the standpoint of personal aid, scientific research and the application of prophylaxis. Studies may be carried on in Italy or in some institute in a foreign country, which the applicant must name when applying for the grant. Applications will be considered from physicians who are connected with related institutions or who give evidence of possessing special preparation in either one of the fields indicated. The amount of the grant and the period of study required will be fixed, from time to time, by the minister of the interior.

New Legislation in Regard to the Sale of Alcoholic Beverages

The new public safety law contains several provisions which establish, among other things, that the manufacture and deposition of insalubrious and dangerous material may take place solely in prescribed localities and in accordance with fixed regulations; in addition, that the sale of alcoholic beverages, though made in hotels, restaurants or private circles, must always be authorized by a special license to be issued by the public safety authorities, and if the percentage of alcohol in a beverage exceeds 21 per cent, a selling permit must be secured from the prefect. The ambulant sale of alcoholic beverages of whatever percentage is prohibited, and the sale of such beverages to minors under 16 years of age is forbidden. The sale of beverages with an alcohol content in excess of 21 per cent is absolutely prohibited on holidays. The manufacture, possession or sale of absinth is likewise prohibited.

NETHERLANDS

(From Our Regular Correspondent)

May 15, 1927

Medical Examination as to Aptitude for Sports

A medical bureau the object of which is to offer an opportunity for medical examination as to aptitude for participation in various sports has been established at The Hague. Professor Sleeswijck, in his dedicatory address, outlined the purposes of the bureau, which are to avoid the ill effects of sports, supervise training and control the effects of sports on the organism. The executive committee comprises a representative of the medical society for physical education, a medical practitioner of The Hague, a school physician, and a representative of the athletic societies. A similar undertaking has been announced in Amsterdam.

Dental Service in the Schools

Following the example of other cities, Rotterdam is planning to organize a dental service in the schools, which will not only comprise an inspection service but also provide gratuitous treatment for children who obtain the consent of their parents. It is estimated that the annual expense involved will amount to about thirty cents per pupil.

International Congress of the History of Medicine

The sixth International Congress of the History of Medicine will be held at the University of Leiden (Leiden) and at Amsterdam, July 18-23. In Amsterdam there will be organized for the occasion an important exposition of paintings and books pertaining to anatomy and the art of healing.

Milk Hygiene

A society has been created in Amsterdam the object of which is to improve conditions surrounding the production, shipment and sale of milk in the region about Amsterdam. With this purpose in view, it proposes to organize a milk control center. It will endeavor to regulate the question of selling price, and will seek to develop the milk-producing organizations and to insist on the value of a good water supply for milk producers. It will also establish a supervision of stables in order to discover diseased animals and will organize an instruction center for the dissemination of knowledge concerning the establishment and management of stables.

Treatment of Leukemia

A philanthropist has established a prize of $50,000 (125,000 florins) for the best work on the treatment of leukemia. A committee composed of Professors Naegeli (Zurich), Van den Berg (Utrecht), and Snapper (Amsterdam) will judge the value of works presented. Competitors must send in their works so as to reach Prof. Hymans Van den Berg, Medical Clinic, Utrecht, Netherlands, by March 1, 1928. The amount of the prize will be doubled in case a member of the family of the founder of the prize, at present stricken with myeloid leukemia, shall be cured by the therapeutic method described in the prize work.

A New Publication

The Netherlands Association for Combating Rheumatism, to the founding of which reference has been previously made, has issued the first number of the review *Rheumatiek*, which will be the organ of the new association.

Opportunities for Vacation Study of Medicine

The association of medical students and the faculty of medicine of Utrecht have taken action with a view to increasing the opportunities for practice work during the course of medical training. They have addressed a petition to the directors of the various civilian hospitals requesting that students of sufficiently advanced standing be permitted to assist in the hospital services of the various cities during the Christmas, the Easter and the summer vacations.

A Council on Medical Ethics

The lower house of parliament has begun discussion of a bill providing for the creation of a council on medical ethics to be established on a basis similar to that of the existing council on legal ethics. The scope of this medicojudicial organization is expressed in the first article of the bill, which states that any physician who becomes guilty of an act calculated to impair the general confidence inspired by the medical profession, who commits a tort bringing damage to a third party, or who gives evidence of marked incapacity, is subject to a special penalty distinct from any damages that may be recovered by process of law. The penalties thus imposable are warning, censure, fine up to $800, deprival of the right to practice medicine for the period of one year, and cancelation of the right to practice.

Furthermore, the council would have the right to deprive of the privilege of practicing medicine physicians suffering from mental or organic diseases incompatible with the practice of the art. The council would be a body that would derive its authority from a central body having the powers of an appellate court. For the application of the three last mentioned penalties (imposition of fines and denial of the right to practice medicine), the civil court of jurisdiction must approve the sentence imposed by the council. The council would be composed of physicians and a jurist. During the course of discussion in the chamber, differences of opinion were expressed as to the rights, duties and privileges that should be accorded to the jurist as a member of the council—whether he should be the chairman or the secretary—and also as to need or feasibility of legislation of this character. Following the expression of the many divergent opinions, the chamber decided to withdraw the bill from discussion and to seek the opinion of the special commission. The Nederlandsche Maatschappij tot Bevordering der Geneeskunst had sent to the chamber a petition in which it urged that the president of the council be chosen from among the physicians and should not be a jurist.

Death of Prof. J. De Bruin

Professor De Bruin, one of the foremost pediatricians in the Netherlands, has just died. His principal works were studies on infantile scurvy and on cerebrospinal meningitis. He was one of the founders of the Netherlands Pediatric Society.

The International Congress of Anthropology

Next September will be held the triennial congress of the international institute of anthropology. The Netherlands national bureau of anthropology, of which Dr. Kleiweg de Zwaan is the president, is entrusted with the organization of the congress. At the same time, the international federation of eugenic organizations will convene in Amsterdam. The papers will be divided among the following sections: (1) physical anthropology, (2) ethnography and ethnology, (3) heredity and eugenics, (4) sociology and criminology, (5) the prehistoric period, and (6) folklore.

Dr. Charles Davenport, director of the Carnegie laboratory for experimental evolution and of the Eugenics Record Office at Cold Spring Harbor, will speak on the crossing of races.

BERLIN

(From Our Regular Correspondent)

June 11, 1927.

Meeting of the German Surgical Society

(Continuation)

Clairmont of Zurich discussed the question of to what extent the standpoint of the referring physician in an operation for acute appendicitis was to be considered. In 1,293 cases there were 280 (more than 20 per cent) wrong diagnoses. The speaker emphasized that the fact did not constitute a reproach to the practicing physician. It was eminently desirable that even the suspicious cases should be referred to the clinic or to the hospital as soon as possible. It was the duty of the clinic (if possible, in agreement with the physician) to decide on the indications for an operation. Similar views were expressed by Konig of Wurzburg, who called attention to a similar situation with regard to patients with gastric ulcer, referred to the clinic, in whom the indications for the operation can usually be decided on only after a clinical observation extending over a considerable period; by Anschutz of Kiel, who stressed the great responsibility of the practitioner in referring the cases, and the equal responsibility of the clinic in refusing to operate; by Meisel of Constance, who, to avoid errors in diagnosis, and especially the confusion of disorders of the lungs and the pleura, makes a roentgenologic examination in every case as a matter of routine, and by de Quervain of Bern, who emphasized that the physician referring the case must never be disavowed. Borchard of Charlottenburg called attention briefly to the possibility of confounding appendicitis and osteomyelitis of the inner table of the pelvis.

With reference to the abdominosacral operation in high placed rectal carcinomas, with preservation of the sphincter muscle, Borchers of Tubingen demonstrated the technic worked out by Perthes (now deceased), in which the advantages of the combined procedure were emphasized. The operation begins from below with exposure of the rectum; the patient is then made to assume the dorsal position; the abdomen is opened and the tumor is delivered by means of two traction bands. Resection follows after ample mobilization of the flexure.

The third main topic dealt with the present status of surgery of the joints, the principal speaker being Payr of Leipzig. In addition to the primary consequences of a joint injury there are secondary changes such as loss of cartilage, development of connective tissue to replace lost cartilage, adhesive union of the joint cleft, deformation of the ends of the joints, obstruction caused by osteophytes, and contraction of capsular ligaments. In animal experiments better results were secured in the presence of slight contamination than when the conditions were entirely aseptic, since chemical irritation plays a part in the regenerative process. Payr discussed the various aids in diagnosing joint injuries and joint disorders particularly roentgenologic procedures. In addition to roentgenograms taken from two different directions, diagonal exposures are often necessary. He mentioned also the determination of the presence of foreign bodies in the deeper tissues, loose bodies in joints, foci, stereoptic photographs, the use of contrast mediums, auscultation and endoscopy, and emphasized the importance of blood tests, the determination of the hydrogen ion concentration, the significance of injections of tuberculin, and excision of the capsule He referred to the importance of latent infection and to the research methods for discovering it In connection with the indications for operative intervention, he emphasized the difference between a healthy joint with a local mechanical disturbance and a joint that has been seriously injured Under some circumstances diagnostic explorations cannot be avoided *The age and the social status of the patient are factors to* be considered Before the operation, the whole operative plan must be thought out—whether the joint itself or other members of the kinetic group are to be attacked, and whether the measures to be resorted to shall be extra-articular or intra-articular, surgical or nonsurgical Payr divides the cases into three fundamental types (1) restoration of form and function; (2) sacrifice of a diseased joint, and (3) contemplated destruction of an anatomically sound but useless joint. Payr discussed then the general technic of joint operations: narcosis by inhalation anesthesia or by conduction anesthesia, importance of asepsis and hemostasis, avoidance of the introduction of foreign bodies of any considerable size, the use of living tissue as far as possible for the restoration of lost tissue, the skin incisions, and methods of opening (conservative attitude toward muscles and nerves, likewise avoidance of injuries to cartilage and articular ligaments) Especially important is the after treatment early movement in the case of joint fractures, every forced movement is a grave mistake but active and passive movements, to be executed by the patient, after the wound has healed, from the tenth day on are beneficial Subsequently, Payr discussed "closed" joint injuries and their sequels, fractures of the neck of the femur, luxations (operative intervention in habitual and irreducible luxations, extra-articular and intra-articular interventions, reparation, resection, plastic restoration), laceration of articular ligaments, internal injuries and pathologic conditions of the meniscus He emphasized the importance of suturing the ligaments but recommended rather the removal than the suturing of the meniscus He devoted a few words to chondropathies, partial necroses, movable bodies in joints (removal of the underlying stratum), chronic effusions, jerking and snapping joints, and amphiarthrosis and flail joints. Open joint injuries should be treated by excision of the infected foci and primary suturing (600 primary cures in 962 cases). He then took up joint disorders of infectious and noninfectious origin (constriction hyperemia, puncture, surgical intervention, phenolized camphor, plastic treatment), osteochondrotrophopathies (malacias), deformities of the joints, ankylosis (caution in the presence of tuberculosis; often more difficult to make a joint sufficiently rigid than it is to mobilize it), tumors and congenital malformations.

Marriages

Joseph H. Greenberg, Toronto, Ont, Canada, to Miss Matilda Friedlander of Brooklyn, June 14

Lawrence A Dondanville, Moline, Ill, to Miss Eva Catherine Ender of Deerfield, June 15

Cyril Vincent Lundvick, Tacoma, Wash, to Miss Kathleen Parshall of Seattle, June 11

Chester Alphonsus Regan to Miss Helen Bell Winklesky, both of Seattle, June 15

Arthur M Kraut to Miss Ophelia Hass, both of Jersey City, N. J, June 8

Benjamin Fosse to Miss May Lear, both of Beloit, Wis, *June 21*

Deaths

Charles Franklin Hoover ⊕ Cleveland, Harvard University Medical School, Boston, 1892, past president of the Association of American Physicians, and the Cleveland Academy of Medicine, chairman of the Section on Practice of Medicine of the American Medical Association, 1907-1908 and member of the American Society for Clinical Investigation, assistant in medicine 1894-1895, instructor in physical diagnosis and director of clinics, 1895-1896, professor of physical diagnosis, 1895 1909, and since 1909 professor of medicine, Western Reserve University School of Medicine, served in France during the World War, visiting physician to the Cleveland City Hospital 1894 1907, and chief of the medical staff of the Lakeside Hospital, where he died, June 15, following a long illness, aged 61

Henry Alphonsus Callahan ⊕ Captain M C, U S Army, Washington, D C, Harvard University Medical School, Boston 1906 member of the Medical Association of the Isthmian Canal Zone, served during the World War and in 1920 was appointed a captain in the regular army medical corps, aged 47, died, March 20, at Fort Totten, N Y of *cerebrospinal meningitis*

Frank Tyler Fraser Stephenson ⊕ Detroit, Detroit College of Medicine and Surgery, 1901, member of the American College of Physicians, lecturer on organic and inorganic chemistry at his alma mater, served during the World War on the staff of the Providence Hospital where he died, May 14, following an operation for appendicitis aged 52

James Samuel Goetz ⊕ Omaha, Miami Medical College, Cincinnati, 1900 assistant professor of medicine and chairman of the department of therapeutics University of Nebraska College of Medicine, on the staffs of the Immanuel and Wise Memorial hospitals aged 48, died suddenly, June 7 of myocarditis and acute nephritis

Leonard Huntress, Lowell Mass, Medical Department of Columbia College New York 1874 member of the Massachusetts Medical Society trustee of the State Almshouse and Farm for twenty five years member of the school board and chairman of the board of health for several years, aged 78 died June 3 of heart disease

John Roseman Marshall ⊕ Sheffield, Ill Rush Medical College Chicago 1896, formerly member of the school board and board of health, on the staff of the Julia Rackley Perry Memorial Hospital, Princeton Ill aged 55, died, June 23 at the Presbyterian Hospital, Chicago, of cysto ureteritis, pyelonephritis and pyemia

Edwin F Kamerly, Jr ⊕ Philadelphia University of Pennsylvania School of Medicine, Philadelphia 1891 on the staff of the Frankford Hospital, and formerly on the staff of the Medico-Chirurgical, and Philadelphia General hospitals aged 58 died, June 21, at the Samaritan Hospital following a colostomy

Herbert George Rockwell, Amherst Mass University of Vermont College of Medicine Burlington 1896 member of the Massachusetts Medical Society on the staff of the Pratt Health Cottage of Amherst College, served during the World War, aged 55, died suddenly, June 25 of cardiac embolism

Lewis Allen Griffith, Upper Marlboro Md College of Physicians and Surgeons, Baltimore 1879 member of the Medical and Chirurgical Faculty of Maryland formerly member of the state board of medical examiners and board of health, aged 68, died, June 23, of heart disease

Robert Quarles McClure, Texarkana, Texas Medical Department of the Tulane University of Louisiana New Orleans, 1901, member of the State Medical Association of Texas, aged 50, died, March 14, at the Michael Meagher Hospital, of pneumonia, following erysipelas

William A Sherman ⊕ Newport, R I, Harvard University Medical School, Boston, 1902, member of the board of health, formerly member of the school board and city council on the staff of the Newport Hospital, aged 49, died suddenly, June 18, of heart disease

John W Scott, St Charles, Minn, University of Wooster Medical Department, Cleveland, 1880, member of the Minnesota State Medical Association, formerly president of the school board and the Citizens State Bank, aged 76, died, May 16, of pernicious anemia

Edmond De Witt Converse, Chicago, Chicago Medical College, 1874, Medical Department of Columbia College, New

York, 1875; member of the Illinois State Medical Society; aged 74; died, in June, of mitral stenosis, chronic myocarditis and chronic nephritis.

Albon Ellsworth Fichtner ⊕ Johnstown, Pa.; University of Pittsburgh School of Medicine, 1907; served in France during the World War; medical director of a maternity hospital bearing his name; aged 43; died, June 21, of an accidental overdose of chloroform, self-administered.

Ferdinand G. Kneer ⊕ New York; Medical Department of the University of the City of New York, 1887; formerly visiting surgeon to St. Catherine's Hospital, Brooklyn; aged 67; died, June 17, following an operation for acute intestinal obstruction.

John J. Wagner ⊕ Brooklyn; Jefferson Medical College of Philadelphia, 1897; formerly on the staff of the Kings County Hospital; aged 59; died, June 11, at the Methodist Episcopal Hospital, of peritonitis, following an operation for appendicitis.

Dorris May Presson Kraus ⊕ Needham, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1911; member of the New England Society of Psychiatry and the American Psychiatric Association; aged 38; died, June 22, of carcinoma.

Albert Livingston Stage, Columbus, Ohio; Physio-Medical College of Indiana, Indianapolis, 1896; Ohio Medical University, Columbus, 1900; member of the Ohio State Medical Association; aged 56; died, May 7, of cerebral hemorrhage.

John W. Hays, Albion, Ind.; Medical College of Ohio, Cincinnati, 1872; member of the Indiana State Medical Association; Civil War veteran; past president of the Noble County Medical Society; aged 86; died, June 17, of senility.

Chisolm Tucker Rogers, Tulsa, Okla.; University of the South Medical Department, Sewanee, 1904; resident physician of the Oklahoma Indian Sanatorium, where he died, June 6, aged 51, of tuberculous peritonitis.

Aurelius Daniel Coleman, Mount Willing, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1880; member of the Medical Association of the State of Alabama; aged 78; died, recently, of arteriosclerosis.

James B. Sharp, Union City, Tenn.; Vanderbilt University School of Medicine, Nashville, 1883; member of the Tennessee State Medical Association; aged 74; died, June 20, of myocarditis and angina pectoris.

Rollo Carlton Dugan ⊕ Ottawa, Kan.; University of Minnesota Medical School, Minneapolis, 1890; on the staff of the Ottawa Community Hospital, where he died, June 10, of carcinoma of the larynx, aged 62.

Frances A. Adams, Syracuse, N. Y.; Syracuse University College of Medicine, 1885; on the staff of the Syracuse Memorial Hospital, where she died, June 8, aged 72, of toxic adenoma and myocarditis.

Burleson Staten, El Paso, Texas; University of the South Medical Department, Sewanee, 1903; member of the State Medical Association of Texas; aged 53; died, June 19, of carcinoma of the bladder.

Frederick Lyman McKee ⊕ Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1899; aged 58; died, May 1, at the Hartford Hospital, of chronic nephritis.

Frank M. Rogers, Vergennes, Vt.; University of Vermont College of Medicine, Burlington, 1899; past president of the Addison County Medical Society; aged 51; died, April 5, of lobar pneumonia.

Jeremiah Hawley Leaming, Vienna, Ohio; Cleveland Homeopathic Medical College, 1898; member of the Ohio State Medical Association; aged 58; died, May 26, of cerebral hemorrhage.

Park Lewis McDonald ⊕ Kansas City, Mo.; University Medical College of Kansas City, Mo., 1889; on the staffs of St. Mary's and St. Joseph's hospitals; aged 65; died, June 8, of heart disease.

David A. Patterson, Westfield, Pa.; Rush Medical College, Chicago, 1897; member of the Medical Society of the State of Pennsylvania; aged 59; died, April 6, of chronic interstitial nephritis.

Milton Seymour Feldman, Northville, Mich.; University of Michigan Medical School, Ann Arbor, 1924; aged 28; died recently, at the Spring Hills Sanatorium, of pulmonary tuberculosis.

John W. Burgess, Higginsville, Mo.; Barnes Medical College, St. Louis, 1903; member of the Missouri State Medical Association; aged 56; died suddenly, June 9, of cerebral hemorrhage.

Samuel H. Anderson, Gibsonia, Pa.; Bellevue Hospital Medical College, New York, 1885; aged 64; died, February 28, at the Allegheny General Hospital, Pittsburgh, of cerebral hemorrhage.

Eugene Henry Lynch, San Francisco; St. Louis University School of Medicine, 1919; aged 34; died, June 23, at the Park Sanatorium, of acute dilatation of the heart and chronic myocarditis.

Charles A. Dewey, Rochester, N. Y.; Harvard University Medical School, Boston, 1880; member of the Medical Society of the State of New York; aged 85; died, June 13, of bronchopneumonia.

William Russell Stevens, Abington, Mass.; Tufts College Medical School, Boston, 1906; member of the Massachusetts Medical Society; aged 47; died, June 5, in Boston, of embolism.

Mary E. Towers, Minneapolis; University of Minnesota Medical School, Minneapolis, 1898; on the staff of the Asbury Hospital; aged 70; died, in June, of chronic interstitial nephritis.

Lewis Harris Britton, Caledonia, Ohio; Starling Medical College, Columbus, 1905; member of the Ohio State Medical Association; aged 47; died, June 12, of cerebral hemorrhage.

Robert Pollard Stryker, Newcastle, Va.; Medical College of Virginia, Richmond, 1912; member of the Medical Society of Virginia; aged 38; died, June 13, of pneumonia.

Joshua Samuel Goodwin, Los Angeles; Rush Medical College, Chicago, 1922; member of the California Medical Association; aged 31; died, May 26, of heart disease.

L. G. Dexter, Harwood, Texas; Louisville (Ky.) Medical College, 1893; member of the State Medical Association of Texas; aged 59; died, June 5, of heart disease.

John H. Wolfe, Degraff, Ohio; Columbus Medical College, 1877; member of the Ohio State Medical Association; aged 73; died, June 23, of diphtheria.

Bayard Thistle Keller ⊕ Cuyahoga Falls, Ohio; University of Maryland School of Medicine, Baltimore, 1871; aged 77; died, May 6, of heart disease.

Donald Campbell Meyers, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1888; M.R.C.S., England, L.R.C.P., London, 1889; died, April 20.

Horace Rindress, North Sydney, N. S., Canada; Medical Department of the University of the City of New York, 1895; died suddenly, April 13.

Nicholas N. Wiger ⊕ Seattle; University of Minnesota Medical School, Minneapolis, 1903; aged 48; died, June 6, of cerebral hemorrhage.

Winston Cass Wood, Bessemer, Ala.; Atlanta (Ga.) Medical College, 1881; aged 78; died, June 19, at Lipscomb, of chronic nephritis.

Burrell L. Craddock, Fort Worth, Texas; Memphis Hospital Medical College, 1891; aged 63; died, February 4, of heart disease.

Paul J. Kappes, Milwaukee; University of Bonn, Germany, 1888; aged 64; died, April 24, of gastro-enteritis and myocarditis.

John Hugh Bannon ⊕ Lawrence, Mass.; Baltimore Medical College, 1898; aged 49; died, May 27, of carcinoma of the throat.

John William Maguire, Huntington, W. Va.; Bellevue Hospital Medical College, New York, 1878; aged 73; died, in May.

John Wheeler ⊕ Plymouth, N. H.; Dartmouth Medical School, Hanover, 1898; aged 55; died, June 5, of nephritis.

Joseph W. Taylor, Hartford, Ky.; University of Louisville School of Medicine, 1875; aged 78; died, June 9, of pneumonia.

Stephen Smith Sanger ⊕ Yukon, Okla.; Fort Worth School of Medicine, 1900; aged 52; died, June 3, of angina pectoris.

William Edward Todd, Hagerstown, Md.; Chicago Medical College, 1890; aged 68; died, June 22, of heart disease.

Edward P. Warren, Etters, Pa.; University of Maryland School of Medicine, Baltimore, 1868; aged 79; died, May 18.

Horace E. Deemer, Jefferson, Ohio; Columbus Medical College, 1883; aged 67; died, May 29, of pneumonia.

James W. Cartwright, Murfreesboro, Tenn.; Memphis Hospital Medical College, 1896; aged 69; died, May 17.

William F. Butler, Cayuga, Ind.; Medical College of Indiana, Indianapolis, 1895; aged 70; died, June 5.

George F. Slater, Chicago; Fort Wayne (Ind.) College of Medicine, 1896; aged 52; died, June 19.

The Propaganda for Reform

In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

"VISCOSE" FOR VARICOSE VEINS

The Viscose Company of Los Angeles, California, sells a small amount of a glue mixture with a few rolls of gauze bandages for $30. This combination is sold as a means of reducing varicose veins. Apparently, the Viscose Company also gives medical treatment to those who will come to its Los Angeles headquarters, for, in some of its form-letters, we read:

Leg Trouble

VARICOSE VEINS — ULCERATIONS

Viscose Method gets at the real cause of ulceration, which is usually diminished circulation from swollen inner veins or varicose veins. New external application once a week replaces elastic stocking. Reduces swollen legs. Stops aches and pains. Makes blood circulate. Avoids laying up to heal sores. Results quick and positive while you work as usual. Send now for FREE BOOK. Tells how to get well at home. A. W. Viscose Co., 803 So. Lake St., Los Angeles, Calif.

> "To reduce varicose veins permanently, you should come to Los Angeles for treatment. An injection in the vein puckers the vein and draws it up. . . . The varicose veins disappear without after-effects"

The letter then urges the sufferer, if he is not willing to come to Los Angeles, to buy the mail-order treatment that the concern sells.

The treatment consists of a pinkish gelatin-like mixture, which the company calls "Viscose," together with some rolls of gauze and of crêpe paper. The instructions are to melt the "Viscose" by placing the can in which it comes in a water bath and bringing the water to a boil. When melted, it is to be thinned down to the consistency of thin cream by the addition of hot water. The melted "Viscose" is then applied to the leg, starting with the foot and working toward the knee, application being made by means of a brush. The first application is made directly to the skin and, while the material is still "tacky," gauze is applied, working from the foot up to the knee. Then a second layer of "Viscose" is painted over the gauze bandage and over this one more layer of the gauze is laid. Then a third coat of "Viscose" is applied, and over it, the crêpe paper bandage is wound.

In order that some information might be available regarding the composition of "Viscose," the A. M. A. Chemical Laboratory was asked to analyze it. The laboratory report follows:

LABORATORY REPORT

"One original specimen of Viscose (Viscose, Inc., Los Angeles, California) was submitted to the A. M. A. Chemical Laboratory for examination. The product was of a rubber-like consistency and colored pink. Qualitative tests indicated the presence of zinc oxide, glycerin, a nitrogenous compound and water. The tests indicated the nitrogenous compound to be composed of gelatin rather than 'casein.' Starch, sulphides, sulphates and borates were not found.

"Quantitative analysis yielded the following:

"Nitrogen, calculated as gelatin " (Nitrogen x 6 25)	24.0 per cent
"Zinc oxide	16 6 per cent
"Glycerin and water (by difference)	39.4 per cent

"From the foregoing analysis, it is concluded that the product is essentially a mixture of zinc oxide and glycerin in a gelatin base. The material seems to be little better than white carpenters' glue with glycerin. The name itself is misleading, as viscose is a well recognized chemical substance known for years and used in making caps for covering bottles, for making artificial hog casings and in the manufacture of artificial silk.

"A product similar to the viscose 'glue' of the Viscose, Inc., can be prepared as follows:

"Gelatin	5 parts
"Water	5 parts
"Calamine	4 parts
"Glycerin	6 parts

"Dissolve the gelatin in hot water, add warm glycerin and calamine (which is impure zinc oxide, used because of its pink color). Mix thoroughly and pour into a mold."

THE JOY BEANS LABORATORIES FRAUD

A Piece of Aphrodisiac Quackery Debarred from the Use of the Mails

One Frank Beland of Cairo, Illinois, exploited an indecent piece of quackery under such trade names as "Joy Beans Laboratories" and "Beland Laboratories." He sold a preparation called "Joy Beans," which was advertised under the claim that the product was a sexual tonic. Beland, of course, had no medical or professional training and employed no physicians, chemists or pharmacists His nostrum, according to the government report, was put up for him by Eli Lilly and Company of Indianapolis He had two formulas for Joy Beans, Nos 1 and 2 The ingredients in No. 1 were.

Pepsin	85/100 grain
Potassium Iodide	2 1/2 grains
Carbolic Acid	1/2 grain
Zinc Phosphide	1/4 grain
Powdered Nux Vomica	1/8 grain
Strychnine	1/60 grain
Yohimbin Hydrochloride	1/12 grain
Calcium Carbonate	95/100 grain

The ingredients in Joy Beans No *2* were

Granulated Pepsin	2 grains
Muirapuama Root	4 grains
Powdered Nux Vomica	1/8 grain
Powdered Zinc Phosphide	1/3 grain
Powdered Yohimbin Hydrochloride	1/10 grain
Powdered Strychnine	1/60 grain
Gold Chloride	1/100 grain
Ferric Chloride Crystals	1/3 grain
Methyl Salicylate	Sufficient to flavor

In the stationery sent out by Beland, Joy Beans were described as "a preparation of roots, barks and herbs gathered from all parts of the world" Some of the further claims made for his nostrum were

MEN BE A REAL MAN Let Me Show You How

Are you ageing before your time? Are you always tired? Do you lack the stamina of youth? Have you tried everything and everybody? Then try The world's greatest force building, tonic tablets for men and women. JOY BEANS YOUR MONEY BACK IF NOT SATISFIED. $2.00 per box of 50 beans. 4 boxes $7.00 cash or C. O. D. plus postage. In plain wrapper. Write today. Agents Wanted.

JOY BEANS LABORATORIES (Frank Beland, Prop.),
Dept E, 915 Ohio St., CAIRO, ILL.

> "Joy Beans are a scientifically prepared tonic for assisting nature to rebuild the weak and worn glands and help to restore them to youthful activity in both sexes"
>
> "If you feel your strength failing, don't wait, delay is dangerous, begin taking Joy Beans at once."
>
> "Fills your blood with rich red corpuscles, makes 'fighting blood' the kind that tends to make the weak strong and the strong stronger Fills you with pep."
>
> "The most wonderful vitalizing, strength giving tonic science has as yet produced; a real fountain of youth"

The federal authorities, in looking into this fraud, found that Beland sold his preparation to persons regardless of the symptoms furnished. One letter written to Beland stated that the writer was 81 years old, lacked the stamina of youth, had lost all sexual power and that his prostate gland was in such condition that urine had to be withdrawn by means of a catheter. Beland was told that if Joy Beans would cure these conditions, to send a $2 package. Beland sent it.

As Joy Beans did not contain roots, barks and herbs gathered from all parts of the world, and would not "restore lost manhood," neither would it protect the sex glands from wear and tear, nor build up the glands in 81-year-old men to youthful activity, the business that Beland was engaged in was declared fraudulent and was debarred from the use of the mails.

Correspondence

XYLENE FOR REMOVAL OF WAX

To the Editor.—Recently I had to treat two patients with hands severely burned by the overturning of a pot of hot sealing wax. What promised to be a very painful and tedious task was made easy by the use of xylene.

Absorbent cotton was saturated with xylene and placed over the sealing wax. In a few minutes the wax had softened where it was thinnest and peeled off as the cotton was removed. Over the areas where there was a thicker layer of wax it was necessary to leave the saturated cotton longer and to aid in the removal of the wax by using dressing forceps. In both cases the wax came off without injuring the blistered skin.

Both patients were delighted with the results and neither complained of any irritation from the xylene, a common experience when it is used to remove adhesive plaster.

This use of xylene suggested itself because of the ease with which it softens asphaltum and like preparations in the laboratory.

C. T. Sharpe, M.D., New York.

IMPORTANCE OF VASCULAR PERMEABILITY IN THE RADIOTHERAPY OF CANCER

To the Editor:—In The Journal, Nov. 6, 1926, page 1537, Dr. A. U. Desjardins states, in his article on "Stimulation and Immunity in Radiotherapy," that "the major effect of radium or roentgen rays is a direct one," and that the "false notion that the partial regression of a tumor resulting from irradiation is due to products elaborated in some mysterious way and leading to some vague form of immunity" is based on a misinterpretation or an abuse of the word stimulation.

I must take issue with such statements for the following reasons:

An epithelioma of the scleral conjunctiva, involving the corneal margin and surrounded by hundreds of dilated capillaries, save in the corneal part of the margin which is avascular, was treated with radium for six days. Six days after the last treatment the vascular scleral margin had not advanced any more, while the avascular corneal edge had pushed forward 1 mm. and infiltrated the deep cornea. This was verified by an examination with Vogt's corneal microscope. Nine days later, only a few remnants of the tumor were left either in the scleral or in the corneal part. However, whereas no capillaries formerly existed in the corneal area, dozens of them now had developed, surrounding the remnants of the cancer cells. Three months later, the epithelioma was cured and the vascular inflammation had subsided.

This experience compels me to conclude that: 1. As the scleral margin pushed forward after the irradiation, its healing cannot be the result of any direct action of radium, as there was none at the time. 2. As the corneal area, which normally has no vessels, succeeded in producing them after the irradiation, the presence of a stimulative formation around the corneal border of the epithelioma must be accepted. 3. As the corneal margin of the epithelioma kept on growing when vessels did not exist and disappeared when capillaries developed, the presence of such vessels must be necessary. 4. Since the vascularization of the scleral margin could not stop the growth of the epithelioma before irradiation, the vascular wall must have been changed by the rays. 5. As there were no capillaries during irradiation, and, moreover, when they developed, the corneal margin of the epithelioma vanished, the change in the vascular wall must be an indirect postirradiation result.

The mechanism causing this change in the vascular wall is not known. However, clinical experience, biologic and chemical experiments(Kroetz, Siedamgrotzky, Cramer), and capillary histology and microscopy combine to show that roentgen rays and radium cause a permeabilization of the parietal wall to many substances which could not cross it before. It seems as if the different permeability shown by the different vessels, both normal and pathologic, was not as yet fully realized.

My present working hypothesis for the treatment of malignant tumors is based on the experiments of Mooser of Mexico City, Dujardin of Brussels and the investigations on metabolism in cancer by Warburg of Berlin. All the causes so far brought forward for cancer—(*a*) chronic irritation (mechanical: stenosis and pressure; physical: heat, light, roentgen rays and radium; chemical: arsenic, silver, thallium, coal tar and paraffin); (*b*) chronic infection, tuberculosis, syphilis; (*c*) dyskeratoses and scars—bring about the same result: sclerotization and decreased vascular permeability to internal secretion products, ferments and especially oxygen. The success of roentgen rays and radium is due to the permeability (erythema, edema) of vessels formerly impermeable to oxygen and probably to other protecting substances. Failures of this therapy occur when the vessels are obliterated or too injured.

Gustav Peter, M.D., Mexico City.
Radiologist, American Hospital
and British Hospital.

KOPLIK SPOTS

To the Editor:—In the summer of 1862, I was a medical student in the office of the celebrated anatomist Robert Laughlin Rea. There were several private students in the city, and during the vacation period we attended clinic on Wednesdays and Saturdays, each member of the faculty giving one a month. One day, during Dr. J. Adams Allen's clinic, a woman brought in a small child. It looked like "the last rose of summer," and had a hacking cough, suffused eyes and hot skin. Dr. Allen said, "Beasley, find out what is the matter with that child." Dr. Rea had instructed me in auscultation and percussion, especially on the normal sounds. He had often said, "Get the normal healthy sounds of the lungs and heart fixed in your memory and you'll readily know when they are wrong." We used tactile sense prior to the invention of the fever thermometer.

The chest was resonant, but when I put my ear on the chest I was astounded at the sounds. Not long before I had listened to the chest of one who was suffering from a slight cold, but this was much worse. I said, "A very bad cold." "No," said the doctor; "Avery, see if you can tell me." He did no better. Then turning to me, Dr. Allen said, "Look in the mouth and tell me what you see." I was surprised to find that the inside of the cheeks and the fauces were covered with small red points. That is the first sign of measles, which always begins that way. I learned it from an old lady who was the general nurse in that neighborhood. When I began practice I found that most of the old timers knew it. One I recall who attended only one course of lectures, who said, "When I am called to see a child and it has the snuffles and the eyes are watering, I look in the throat first to see if I shall quarantine."

Several years ago at one of our county society meetings, measles was under discussion. There were present several recent graduates, one a woman. She was up to date and spoke of the Koplik sign as the latest thing in diagnosis. The name was a new one on me; I had never any trouble in the diagnosis for I had always looked in the mouth, and I was ashamed to get up and confess my ignorance. Next day I met one of the members and asked him what was that new diagnostic symptom. He told that a wonderful German, down east, had discovered that before measles made its appearance on the skin it appeared on the inside of the cheeks and fauces. I was amazed, for I had known it when Koplik was a small child.

"There is nothing new under the sun."

George F. Beasley, M.D., Lafayette, Ind.

A NOVEL TRICK TO OBTAIN MORPHINE

To the Editor:—A man giving the name Webster recently called on me, saying that he had been referred to me for treatment by the superintendent of the cement mills here. He claimed that he had to use sulphate of morphine in intestinal irrigations for amebic dysentery, and in support of his statement he presented what purported to be a letter from Dr. ——— of Nashville, Tenn. This supposed letter said that the patient was incurable and that any physician would be doing a kind act to furnish him with 40 grains of sulphate of morphine or prescribe it for him. Dr. ———, by whom the supposed letter was purported to have been written, had, according to the letter, furnished the patient with scales for weighing out the quantity to be used and had given instructions as to dosage. Inquiry showed that the superintendent of the cement mills had not referred the patient to me. I did not fall into the trap. I have notified Dr. ———, whose name this patient used in his efforts to obtain morphine. I am writing to The Journal of the incident, however, in order that it may put physicians generally on their guard against this scheme.

John Asa Gibbons, M.D., Mitchell, Ind.

SODIUM PERBORATE FOR VINCENT'S ANGINA

To the Editor:—In his article on oral lesions due to Vincent's angina (The Journal, April 9, p. 1142), Dr. Joseph C. Bloodgood calls attention to the specific action of sodium perborate. The statement is made that "before trench warfare in France, in 1914, . . . a specific therapeutic agent had not been discovered." Unfortunately, there is a lack of liaison between dental and medical publications; hence I am calling your attention to the original publication.

In a paper read before the El Paso County (Texas) Medical Society in January, 1913, I reported the discovery of the specific action of sodium perborate in the treatment of Vincent's angina. This paper was published in the *Bulletin of the El Paso County Medical Society* in October, 1913 (5:9-14), and in the same month in the *Western Dental Journal* (27:13-18) and republished in the *Dental Digest* (20:478-482, 1914). On page 555 of the fifth edition of Modern Dental Materia Medica, Pharmacology and Therapeutics, Dr. Buckley says: "Dr. Henri Letord, a dentist of El Paso, Texas, is credited with being the first to bring the use of this drug [referring to sodium perborate] before the attention of the medical and dental professions."

I write this letter believing that you will be interested in having a correct record of this discovery.

Henri Letord, D.D.S., El Paso, Texas.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

MALTED MILK NOT A BALANCED DIET

To the Editor:—I would greatly appreciate an expression from you as to the advisability of giving malted milk to babies and growing children. Do you regard malted milk as a *balanced* diet? In your judgment does it provide the five basic food elements—fats, proteins, carbohydrates, minerals and vitamins—in proper proportions?

Charles L. Summers, M.D., Baltimore.

Answer.—It is generally agreed that simple mixtures composed of cow's milk, water and sugar are most suitable as a substitute for breast milk in infant feeding. It has been shown by a number of observers that milk may be dried and still retain a considerable part of its antiscorbutic vitamin, provided it is dried quickly and packed in air-tight containers. On the other hand, it is probable that dried milks, though they may contain vitamins when freshly prepared, tend to lose them if kept for a considerable time before being used. McCollum and Davis believe that scurvy is more likely to occur with milk preparations that have been preserved for a long period.

It might be debatable whether malted milk is a well balanced diet. Analysis shows most of them to be largely carbohydrates, 67.95 per cent of the mixture being sugars, lactose, maltose and dextrins. The fat protein and ash contents are moderate in quantity.

For nearly every baby food, one may find a group of happy contented and fat babies who have thrived on it. On the other hand, the same food, when improperly, unwisely or excessively used may have caused rickets, scurvy or diarrhea, or have contributed its share in increasing the infant mortality.

On account of the high carbohydrate content of malted milk, fermentation and diarrhea may result from its use. Some older children and adults relish it as a beverage, and in acute illness it may be served as a nutritious food.

INDUSTRIAL HAZARD IN PAINTING BY SPRAY METHOD—DUCO PAINT

To the Editor:—The board of education is having some of its interior painting work done by spray guns in addition to having painting work done by brushes. A question has been raised as to the effect on the health of workmen operating these spray guns, using lithophone paint in the one case and lead and oil paint in the other case. It has been said that these operators are exposed to lead or benzene poisoning.

James F. Brown, Cleveland.

To the Editor:—Please tell us what is the best type of gas mask to be used by workers in Duco paint shops. Is there a standard code for ventilation, etc., for these Duco shops? If you do not have this information available could you tell us where we could find it out? Please omit name.

M.D., Minnesota.

Answer.—The literature concerning the hazards from the use of lead paint by means of mechanical sprays is relatively meager. Perhaps the best summary of the subject is that by Alice Hamilton, author of "Industrial Poisons in the United States," published by the Macmillan Company, 1925.

> There are two changes [says Dr. Hamilton] which have come fairly recently in the painters' trade, both of which have spread with great rapidity and both of which result in adding decidedly to the dangers of the industry. These are the use of quick-drying paints for interior decoration and the use of the so-called spray gun for applying paint. The spray method of painting and varnishing has increased in popularity with bewildering rapidity during the last few years. The danger is obvious. *A finely divided spray of lead paint or of paint which is lead free* but contains volatile thinners of the petroleum or coal tar series is a very difficult thing to handle without poisoning the air which the sprayer must breathe. Agricultural machinery, automobile bodies and furniture are now usually painted by spraying, and although an effort is made to safeguard the painter by the provision of cabinets with exhaust ventilation, the practical difficulties are great. A much greater problem is presented by the use of the spray gun in painting walls and ceilings and shelves and mantelpieces inside buildings.

About five years ago, N. C. Sharpe of the Toronto University "published a report of a very careful investigation of the hazards involved in using lead paint by the spraying method. He made up a paint with white lead for pigment, turpentine, linseed oil and benzine for the liquid vehicle, and this he used in a spray with a pressure of 35 to 55 pounds per square inch. Specimens of air were collected by Duckering's method, the samples being taken at the level of the painter's nose and mouth. Sharpe found that when lead paint is used in spraying the interior of buildings there is a decided danger of lead poisoning, but in spraying small objects inside a cabinet this danger may be prevented, provided there is an adequate exhaust properly placed, provided the cabinet is deep enough and of proper shape, and provided the object to be sprayed is not too large. If the exhaust is placed above the painter the spray will be drawn up past his face, and if the object is large and the painter stands directly in front of it spraying at a right angle, the spray will roll back toward him in spite of the exhaust.

"Sharpe tested masks, respirators, to see how much protection they afforded to men using the spray gun in interior decoration. 'Masks of comfortable breathing thickness moistened with a 5 per cent solution of sodium sulphide, reduced the amount inhaled from 232 mg. per 10 cubic meters of air to 12.4 mg., and a similar mask, but dry, allowed only 11 mg. to pass through. Both these results are still over the danger line', that is, Legge's limit of 5 mg. per 10 cubic meters of air. A really effective mask Sharpe believes, would not let through enough air to allow the man to do his work. Beating the dried overalls after spraying resulted in the recovery of dust containing from 2.79 mg. to 6.02 mg. of lead."

Lead paint is being used less and less in spraying machines. Quick drying and leadless paints, such as the lithophone paint mentioned by our correspondent, or various paints made from pyroxylin, such as Duco, are the ones coming into more general use. Complaints of ill health have been made from painters engaged in the use of these. In the latter cases, the chief hazard is from the solvents used. It is obvious, of course that in all cases where sprays are being used, irrespective of the paint, a factor of prime importance is proper ventilation.

A considerable amount of work has been done on the safe use of Duco as regards both fire and health hazards by the DuPont Company, Wilmington, Delaware. This has been published in a bulletin, which they will forward on inquiry.

The Universal gas mask, manufactured by the Mine Safety Appliances Company, Pittsburgh, is undoubtedly proficient for the purpose. These workers should be so protected by mechanical means, however, that they need not wear gas masks.

MEDICAL DISCOVERIES BY YOUNG MEN

To the Editor:—Please send me a brief list of the great discoveries made in medicine by comparatively young men, with the age of these men at the time the discovery was made, and the nature of the discovery. Please omit name.

M. D., Pennsylvania.

Answer.—We would suggest the following:

William Harvey described the circulation of the blood in 1628, at the age of 50.

Thomas Bartholinus described the existence of the thoracic duct in 1652, at the age of 36.

Jan Swammerdam observed red corpuscles in frog's blood in 1658, at the age of 21.

John Abernethy was the first to ligate the external iliac artery for aneurysm in 1796, at the age of 32.

Ephraim McDowell performed the first ovariotomy in 1809, at the age of 38.

Joseph Priestley discovered nitrous oxide in 1772, at the age of 39.

Rene Laennec invented the stethoscope in 1815, at the age of 34.

Crawford W. Long performed the first operation with the patient under the influence of ether in 1842, at the age of 27.

William Thomas Green Morton used ether in 1846, at the age of 27.

Lord Lister communicated his successful results in antisepsis to a meeting in 1867, when he was 40 years of age. He had graduated twelve years before.

Robert Koch discovered the tubercle bacillus in 1882, when he was 39 years old.

Von Behring first used diphtheria antitoxin in 1890, when he was 36 years old.

Frederick Banting discovered insulin in 1923, when he was 31 years old.

Madame Curie did her work on radium in 1899, when she was 32 years old.

Darwin did his work on the origin of species at 29 years, and Wallace his at 36 years.

Pasteur's epoch-making discoveries started with his work on ferments when 35 years old.

Servetus published his discovery of the blood circulation when 44 years old.

Eustachius completed his anatomic tables when 28.

Vesalius swept away Galen's anatomic errors with his Fabrica when 29 years old.

Fallopius completed his remarkable discoveries before he died at 39.

Ehrlich discovered mast cells and began his stain work when 23 years old.

Pare performed the first exarticulation of the elbow when 26 and published his book on gunshot wounds when 35.

Jenner began his observations on vaccination when not yet 30.

Lavoisier discovered oxygen when 32.

Neisser discovered the gonorrhea bacillus when 24, and Schaudinn *Spirochaeta pallida* when 34.

Bichat published his treatise on membranes when 28.

Semmelweis recognized the infectiousness of puerperal fever when 29.

Skoda systematized percussion and auscultation when 34.

Widal suggested his typhoid test when 34.

Claude Bernard, when 30, had already started his study of the glycogenic function of the liver.

Von Helmholz, at 26, had already established the law of conservation of energy.

Du Bois-Reymond, at 25, discovered the difference of potential between the cut and the uninjured ends of an excised muscle or nerve, and defined electrotonus.

Velpeau published the first detailed work on surgical anatomy when 28.

Carl Ferdinand von Graefe, when 29, devised the operation for cleft palate and founded modern plastic surgery, and his son Albrecht described keratoconus when 26 and introduced iridectomy in several eye conditions when 27.

Bell began publishing his anatomy when 30.

Hodgkin described the disease still bearing his name when 34.

Ricord established the differentiation of gonorrhea and syphilis when 32.

POULTICES IN PNEUMONIA

To the Editor:—Please let me have your opinion as to the value of poultices in the treatment of pneumonia.

Abelardo Gonzalez, M.D., Templeton, Pa.

Answer.—In the treatment of lobar pneumonia, poultices are probably valueless excepting to the degree to which they might exert an analgesic action against pain in the chest. By no stretch of imagination can one see how applications to the outside of the chest could affect the consolidation characteristic of this disease. In bronchopneumonia, on the other hand, general hyperemia of the chest wall might possibly be beneficial in lessening bronchial congestion, and, in this manner, improve aeration of the lungs, which probably explains the sense of relief that may be experienced.

SAFETY OF STERILIZATION PROCESS

To the Editor:—Please give me what you consider the consensus regarding the safety for surgical procedures of sterilization as done in a National sterilizer, or any similar steam pressure outfit such as is used in homes for canning fruit and vegetables. Please use initials only.

F. E. H., M.D.

Answer.—The steam pressure cooker has been used with safety in the canning of vegetables and meats. The processes involving their use which may be regarded as safe are given in a circular on processing, issued by the Bureau of Home Economics of the United States Department of Agriculture, Washington, D. C. The processes used in the canning of meats and vegetables which may be regarded as safe could be used for sterilization purposes of material used in surgical procedures.

One difficulty with these cookers, as they are sold, is that they are usually equipped with a single pressure gage. It is the opinion of many that such a type of cooker should be equipped with both a thermometer and a pressure gage, and the operator should also know that the two are in agreement. Of course, this precaution is suggested because one instrument will sooner or later get out of order. The thermometer is likely to last a good deal longer than the pressure gage.

One difficulty in using the small pressure cookers is that when they are heated on the stove, as they often are, the heating is rather slow. This does not interfere, however, with the safety of the products processed in them, since the time for processing begins when the holding temperature is reached. Therefore, if a pressure cooker is equipped with a thermometer and a pressure gage and both instruments are correct and in agreement, and the temperature reached (approximately around 115 C.) is maintained for a sufficient length of time, the pressure cooker could be used for the sterilization of material used in surgical procedures.

CONTINUANCE OF SYMPTOMS AFTER PROSTATECTOMY

To the Editor.—A man, aged 72, one and a half years ago had a prostatectomy at a reliable clinic. Now he still has to urinate every hour and has smarting afterward. Kindly advise me about treatment for him. What is "string bladder"?

M. D., Maine.

ANSWER.—The symptoms reported may be due either to a true recurrence or to a cicatricial contraction at the site of the enucleation. A recurrence is rather rare and originates in nodules left within the prostatic lobe. The diagnosis is established by palpation, by the fact that the urethra appears again to be elongated and by cystoscopy. The latter procedure is also employed for establishing the presence of a cicatricial contraction around the vesical outlet. The extent of a true recurrence or of the cicatricial constriction determines whether the obstacle has to be removed by excision through a suprapubic cystotomy or whether an endoscopic operation may be employed to advantage. For the latter intervention any one of the electric prostatotomes devised for this purpose may be used.

The term "string bladder" does not seem to denominate any well defined pathologic condition.

CAMEMBERT CHEESE

To the Editor.—I have been asked if the thick outer portion with the mold which forms the exterior of a Camembert cheese is eatable. I would also like to know what constitutes this mold and whether there is any advantage in eating or discarding it.

M.D., New York.

ANSWER.—The Camembert mold that forms the rind of Camembert cheese is eatable. The Camembert mold ripens the cheese from the outside, whereas in the case of Roquefort cheese the Roquefort mold grows within the cheese and *develops the Roquefort flavor.*

DIATHERMY IN PROSTATIC ENLARGEMENT

To the Editor.—What place, if any, has diathermy in the treatment of nonmalignant enlargement of the prostate; also, is it indicated in inflammation of the gland *with or without gonorrhea? If this treatment has* a place, what type of portable machine is the best and who is the maker? Of course, I refer to cases that have not come to the point at which a surgeon considers an operation indicated.

K. R. PARMENTER, M. D., Colorado Springs, Colo.

ANSWER.—True neoplastic enlargement of the prostate, whether benign or malignant, is not appreciably influenced by diathermy. In microbic inflammation of the gland, diathermy is a valuable therapeutic agent. One must distinguish between the symptomatic relief and the reducing of the inflammatory tumefaction. The latter may not always be accelerated, but the extreme sensitiveness of the swollen prostate and the concomitant rectal and vesical tenesmus are in practically all instances promptly alleviated.

An important factor is the duration of each treatment, which should extend to about thirty minutes. For this purpose tolerance of the rectum must be established. The bowel must be free of fecal matter. This is best accomplished by an oil enema, since medical catharsis is apt to increase the irritability of the rectum. In sensitive patients it will be necessary to obtund the excessive sensitiveness of the prostate and rectum by the previous insertion of a rectal suppository carrying some opiate. In this way, painful contractions of the prostate and seminal vesicles are prevented.

It is a matter of experience that the tolerance of the patient increases with each consecutive treatment. For heating the prostate, especially designed electrodes are used. The indifferent blocked tin electrode is placed on the abdominal skin. For the determination of the dosage, exact figures cannot be given. The operator should be guided by this point: The current is slowly started and increased until the patient reports a distinct sensation of warmth but not of heat. The latter instance calls for reduction of the current.

While skepticism toward excessive claims is justified, still diathermy, if properly applied, has pronounced merits. In chronic cases it is an indispensable component of the treatment. Any portable machine manufactured by firms whose advertisements are scrutinized and accepted by the American Medical Association will answer the demands of the operator.

PANCREOLS

To the Editor.—A member of my staff recently had a patient who had been advised to take Pancreols for diabetes. On page 44 of the enclosed pamphlet you will see what is going on. Can you report on this product and on the firm which exploits it?

W. W. P., M. D., New York.

ANSWER.—The pamphlet is a piece of advertising "literature" of the Drug Products Co., Inc., dealing, among others, with their product Pancreols (formerly called Insulols), claimed to be rectal suppositories "Containing Specially Prepared Desiccated Pancreatic Hormone-bearing Substance Containing the Active Principle of the Islands of Langerhans." In effect this preparation offers insulin for rectal administration.

A *note on Insulols* (the former name of Pancreols) appeared in THE JOURNAL, July 26, 1924, p. 289, pointing out that scientific evidence had not been offered for the value of this product. Reference was made to an article in THE JOURNAL, Sept. 1, 1923, p. 752, reporting the unsuccessful use of insulin administered in rectal suppositories, but attention was called to another article (THE JOURNAL, July 26, 1924, p. 301) which indicated that in animals absorption might occur in some instances. The work of Labbe, Nepveux and Forsans (*Bull. et mém. Soc. méd. d. hôp. de Paris*, Oct. 24, 1924, p. 1431), who found the rectal administration of insulin of little or no value, as compared to the subcutaneous route, against glycemia, glycosuria or acidosis, appears to establish the inefficiency of this method. THE JOURNAL (Feb. 25, 1927, p. 652) in an editorial comment on "The Uselessness of Insulin by Inunction" classes the administration of the drug by rectum among other methods which are "either mechanically difficult, inconclusive, inconstant, or wasteful of the drug."

No preparation of the Drug Products Co., Inc., has been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies. A number of this firm's products have been reported on unfavorably, viz. Pulvoids Calcylates (THE JOURNAL, Sept. 9, 1916, p. 827; Propaganda for Reform **2**:85), Pulvoids Calcylates Compound (THE JOURNAL, June 14, 1919, p. 1784; Propaganda for Reform **2**:226), and Pulvoids Natrium Compound (Annual Reports of the Council on Pharmacy and Chemistry, 1916, p. 69; Propaganda for Reform **2**:108).

PARAPLEGIA DURING TREATMENT FOR SYPHILIS

To the Editor.—Will you kindly give your opinion regarding the sudden development of paraplegia (transverse myelitis) during intravenous treatment of syphilis with arsphenamine? Is there recent literature on the subject? Although I have had the opportunity of observing a large number of syphilitic patients over a period of years I have not encountered this condition until the last two years, since which time I have seen several. This has impressed me as being a type of Jarisch-Herxheimer reaction. Please omit my name.

M. D., California.

ANSWER.—The development of a transverse myelitis following the administration of arsphenamine is certainly exceptional and there are practically no reports of such a condition in the literature. The nearest approach to it is a report of an acute ascending myelitis by Viets (*Boston M. & S. J.* **188**:895 [June 7] 1923). In that article the author discusses the possibility of the occurrence of an acute myelitis similar to the hemorrhagic encephalitis that is known to occur, apparently as a direct result of the arsphenamine. The Jarisch-Herxheimer reactions strictly are skin manifestations that occur only in the early secondary stage of syphilis. The so-called neurorecurrences, in which cranial nerves are most often affected, are probably syphilitic and not due to the drug administered. In considering the possibilities it must not be forgotten that myelomalacia, often called transverse myelitis, is not an uncommon result of thrombosis of syphilitic vessels in the cord and develops as a rule during the late secondary stage. It seems more probable that the cases observed were of this nature than that they were reactions *due to the arsphenamine.* Villaverde (*Siglo méd.* **79**:654 [June 11] 1927) has seen transverse myelitis result from treatment of neurosyphilis in a considerable number of cases. In these instances, however, the treatment was administered by the intraspinal route.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

Alaska: Juneau, Sept. 6. Sec., Dr. Harry C. DeVighne, Juneau.

National Board of Medical Examiners, Parts I and II, Sept. 14-16. Applications should be made by August 14. Sec., Dr. John H. Rodman, 1600 Walnut Street, Philadelphia.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. Charles Duncan, Concord.

Porto Rico: San Juan, Sept. 6. Sec., Dr. D. D. Biascoechea, *Box 804, San Juan.*

South Dakota: Huron, July 19. Dir. Medical Licensure, Dr. H. R. Kenaston, Bonesteel.

West Virginia: Martinsburg, July 26. Commissioner, Dr. W. T. Henshaw, Charleston.

Colorado January Examination

Dr. David A. Strickler, secretary of the Colorado Board of Medical Examiners, reports the written examination held at Denver, Jan. 4, 1927. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. Of the 6 candidates taking the physicians' and surgeons' examination, 4, including 3 osteopaths, passed and 2, 1 undergraduate and 1 osteopath, failed. Fourteen candidates were licensed by reciprocity and 2 by endorsement of their credentials. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
St. Louis College of Physicians and Surgeons	(1925)	88.3
Osteopaths		76.4, 82, 88.3

FAILED

College	Per Cent
Undergraduate	73.8
Osteopath	62

Book Notices

Muscular Contraction and the Reflex Control of Movement. By J. F. Fulton, B.Sc., M.A., Ph.D. Cloth. Price, $10. Pp. 644, with illustrations. Baltimore: Williams & Wilkins Company, 1926.

Not since the publication of Sherrington's Integrative Action of the Nervous System has such a monumental scientific compilation and critical analysis of muscular contraction and the nature of its reflex control been published. The volume details the advances in this field since 1906 and is a companion volume to Sherrington's classic. Full description is given of advances made into the mode of action of the central nervous processes on the basis of modern methods of attack. Part I, dealing with the nature of the contractile response of individual skeletal muscle fibers, is based on the author's own researches. The extensive bibliography indicates the grasp of the literature possessed by the author. The book fulfils a want long felt in physiologic circles. It will furthermore be heartily welcomed by those few clinical neurologists who themselves are interested and active in helping to unravel the intricacies of nervous action in health and disease. For such the book is indispensable. The general practitioner would find it much too technical and "scientific."

Obstetrics for Nurses. By Joseph B. De Lee, A.M., M.D., Professor of Obstetrics at the Northwestern University Medical School. Eighth edition. Price, $3 net. Pp. 635, with 267 illustrations. Philadelphia: W. B. Saunders Company, 1927.

The fact that this book has reached its eighth revision and has been reprinted thirty-seven times during the last twenty-three years is an indication of its popularity. And there is no doubt that its popularity is well deserved. The present volume is somewhat larger than the previous ones, and is enriched by the addition of many new illustrations. Special attention is again devoted to the subjects in which nurses can be of particular help in obstetrics; namely, prenatal care, puerperal infection, the toxemias and the complications of labor. The author does not lose sight of the fact that the majority of births still occur in the home, and the nurses are explicity instructed in the care of the patients there. As in previous editions the text is down to date and includes everything that can be of use to a nurse who has the care of an obstetric patient. The illustrations are most abundant, unusually clear and very instructive. Those of the methods of identification of the baby show that at the Chicago Lying-In Hospital five different methods of identification are used for each baby; hence the danger of exchanging babies is reduced to a minimum. The section on analgesia includes a detailed account of Gwathmey's synergistic method, and the section on anesthesia contains a discussion on ether, chloroform, nitrous oxide and ethylene. In the section on the preparation of the patient, the author discusses not only the usual scrub and flush method but also the use of iodine and of mercurochrome-220 soluble. The author devotes a number of pages to pelvic mensuration. In addition to giving the usual information, he cites specific cases of contracted pelvis and discusses the kind of labor to be expected in these cases. Such a discussion makes the subject of pelvic measurements very practical. The chapters on the care of the babies, especially the one on premature infants, are most instructive. Even a hasty perusal of the book will indicate why it is the most used textbook for nurses. It is written in an easy, delightful style by a person who, for more than thirty-five years, has been teaching not only students of medicine and graduate physicians but also nurses. The information given is practical and is of use to the nurse in the most elaborate maternity hospital as well as in the dirtiest hovel. The continued popularity of the book is certain. It is unfortunate, however, that better paper was not used.

La cesárea extraperitoneal y la transperitoneal suprasinfisaria sus modalidades técnicas y sus finalidades terapéuticas. Por Mateo Carreras. Paper. Pp. 106, with illustrations. Madrid: Javier Morata, 1927.

The purpose of this book is to familiarize Spanish-speaking physicians with the low, cervical cesarean section. The author first reviews the history of the development of the cervical operation and discusses nearly every type of cervical cesarean section both extraperitoneal and intraperitoneal. In addition there is a description accompanied by illustrations of the recent exteriorization operation of Portes, which is a modification of the Gottschalk operation. Not only are the different forms of the operation discussed but also such matters as anesthesia, extraction of the fetus, tamponade of the uterus, sterilization and drainage. Among the indications for the operation the author considers not only contracted pelvis but also placenta praevia, eclampsia, prolapse of the umbilical cord, cervical cancer and transverse presentations. The book is written in a clear and simple style, the type is large and distinct, and the illustrations are instructive. Mention is made of Wetterwald's recent review on rupture of the uterus after the cervical type of cesarean section. Unfortunately, the author has limited his sources of information to German, French and Spanish authorities. Americans, particularly De Lee and Beck, and the English, especially Munro Kerr, have contributed to the improvement of the cervical operation. Regardless of this the book will most likely and properly enhance the popularity of cervical cesarean section among Spanish-speaking physicians.

Applied Refraction. By Homer Erastus Smith, M.D., Assistant Surgeon, Manhattan Eye, Ear and Throat Hospital, New York City. Cloth. Price, $2.75. Pp. 131, with 9 illustrations. New York: William Wood & Company, 1927.

This is not a compendium nor yet a textbook on refraction but rather the observations gathered through thirty years of experience by a clinical ophthalmologist. It is a chatty, discourseful book written for his brother practitioners.

Tiger Trails in Southern Asia. By Richard L. Sutton, M.D., Sc.D., LL.D., Professor of Dermatology, University of Kansas. Cloth. Price, $2.25. Pp. 207, with 115 illustrations. St. Louis: C. V. Mosby Company, 1926.

For the most of us life is a round of drab reality. If we want to be devilish we take an afternoon off for a game of golf or go to a baseball game. The limit of adventure is a week in the woods, where we catch a few small game fish and have our lunches out of skillets and brag about it, more or less, for the rest of the year, or—event of a lifetime—a tourist cruise to the West Indies or to the Mediterranean. Sutton is made of no such Lilliputian stuff. He did all these things when he was young in sport. He has long since exhausted the hunting fields of America. Now, having caught and shot everything of size that is not protected by the game laws in our country, he has in later years sought larger thrills and has picked out for his excursions the out-of-the-way haunts of game of the earth. He is a wise man, or perhaps he has acted wisely in spite of himself; for his great hunting expeditions are evidently in response to an instinctive urge that was irresistible. It has taken him into some rare places, given him some rare experiences for an apparently staid doctor, and enabled him to enjoy adventures that are beyond the dreams of the rest of us, who hunt, instead, the pediculus, the acarus and the microbe. Wise man—and tough—for none other would have had the hardihood to undertake, or the endurance to survive, his hunting trips.

Many of us are familiar with the exceedingly interesting account of his trip to the plateau of British East Africa after lions and elephants and other big game there. Now he has sought even more remote haunts of big game, and in this book records his hunting trip in southeastern Asia. This journey took him into the wilds of French Indo-China after tigers. Incidentally he got all sorts of other dangerous and interesting game, including elephants; but as the elephants there only run about five or six tons they do not excite much interest for him—it takes about a 16 ton elephant, the kind they get in Africa, to give him excitement. Sutton has developed to the point where his hunts, as a matter of course, are successful. This one was so to a notable degree. Anybody going on the same sort of journey can do well to get the advice about how to do it that he gives in this book. The book gives also an exceedingly interesting account of many things pertaining to such a journey. It is interesting as hunting, interesting in its accounts of wild animals, and interesting as travel. The style is good and lively, with none of the braggadocio that is apt to creep into such books. It is not only a book to be recommended to the hunter but it will be highly interesting, as well as valuable, to every doctor, to show him how a man, even in our quiet sort of occupation, can get fun out of life if he tries.

We are glad he went for his own sake and in order that he can tell us about it. We look forward with keen anticipation to his next volume "Trailing the Man-Eating Savages of the Upper Amazon."

Concerning Aneurysms. The Third Gordon Bell Memorial Lecture Delivered Before the Winnipeg Medical Society, on April 1, 1926. By Oskar Klotz, Professor of Pathology and Bacteriology, University of Toronto. University of Toronto Studies, Pathological Series. Paper. Price, 50 cents. Pp. 74. Toronto: University of Toronto Press, 1926.

In this lecture, Klotz has once more brought together the results of studies of diseases of arteries, a subject in which he has displayed considerable interest for many years. The evolution of our understanding of aneurysm, the history of syphilis and a discriminating consideration of the possibility that its first appearance in Europe was due to importation from America by the sailors with Columbus and other pioneer explorers are presented briefly in an account that is enjoyable reading. There are also excellent descriptions of the various types of arteriosclerosis which should serve the demands of medical students far better than does the treatment given them by the textbooks of pathology that have so far appeared in English. Such descriptions are, moreover, incidental, for the main theme is aneurysms. The English is a little careless in spots; for example, "the syphilitic process upon arteries," and "in consequence to inflammatory processes" (p. 26); "the bacterial mass in the latter instance formed the embolus which is microscopic in size and which occludes . . ." (p. 49). This feature may, however, be concerned solely with the hazards of publication. Aneurysms of the heart and of the leaflets forming the heart valves have no place in this work. The splendid work of Vestberg in 1897 on acute dissecting aneurysms of the heart and the important relation the anatomic structure of the periaortic space of Vestberg bears to such aneurysms are not mentioned. Recent studies of the possible rôle of lymph channels in the spread of syphilis in the aorta and of the mechanical forces concerned with the peculiarities of its location and distribution in the root of the aorta are certainly of great interest, and they merit, perhaps, more notice than they have received in a monograph such as this and so largely a review of literature. Nor are there any comments on what takes place in the intramural channels, or in the walls of branches of the aorta when the aortic wall is split by dissecting aneurysms, where such branches have their origin. The importance of this sequence of dissecting aneurysm of the aorta and the possibility that symptoms of great value for its recognition during life are caused by disturbances of circulation in the regions supplied by such branches are most intimate essentials of this topic. One naturally searches for the numerous personal experiences of the author and cherishes them when they are found. Among these are details of his knowledge of syphilis in Brazil, his search for the parasite of syphilis in diseased aortas, and observations of eleven aneurysms in children under 15 years of age. These are among the important matters that add greatly to the value of this presentation With the ending of its reading, there comes an earnest desire that from his pupils and the author the medical profession may still be served with the results of additional investigations and studies of the diseases of human arteries

Surgical Nursing and the Principles of Surgery for Nurses By Russell Howard, C B E, M S, F R C S, Surgeon, London Hospital Fifth edition Cloth Price $3 Pp 320, with illustrations New York Longmans, Green & Company, 1926

This book is based on lectures to the probationer nurses at the London Hospital An effort is made to instruct them in the fundamental principles of surgery and in the nursing of surgical patients There is a rather detailed discussion of such surgical problems as infections, inflammations, wounds, specific infections, hemorrhage, shock, new growths and burns The operative nursing and care of patients after operations on the various regions of the body are considered, including fractures and the special care of infants Bandaging and massage, with numerous prescriptions used in the postoperative care of these patients, are added

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1926, with comments that have appeared in The Journal Cloth Price, $1 Pp 73 Chicago American Medical Association 1927.

This volume contains the unabridged Council reports that have been adopted and authorized for publication during 1926 Some of these reports have already been published in The Journal, others have never been published elsewhere The book thus makes available the actions of the Council on all products which have been denied admission to New and Nonofficial Remedies or which have been omitted from that book during the year In addition, the book contains several special reports authorized by the Council in 1926

Reports are given on the following articles found not acceptable for New and Nonofficial Remedies Allonal, Animasa, three benzyl benzoate preparations, Ceanothyn, Cresog, Firma Chloro, Idozan, Malt Nutrine, Murarsenide, Naftalan, Neo-Reargon Nontox, Numoquin, Oleosolution, "Pabst Extract—The 'Best' Tonic," Phenoseptine Cones and Phenoseptine Powder, Pollen Antigen Spring Type-Lederle, Rad-X-Solution A, Rad-X-Solution B, Robes' Antirheumatic Injections, Sodium Methylarsenate (De Marsico), Ster-Alco, Sulcitacium, Tetradol, Thymo-Borine, Toxivi, Toxok and Triophos Besides these there are a number of reports on articles that have been omitted from N N R

The volume also contains the following special reports of current interest to physicians a report on the status of bacillus acidophilus and bacillus bulgaricus therapy, on the basis of which the N N R article on Lactic Acid-Producing Organisms has been revised and rewritten, a report dealing with the esteem in which antistreptococcus serum is now held by leading surgeons, gynecologists and obstetricians, prepared by Dr Emil Novak on the basis of the answers to a questionnaire sent to representative members of these groups, and a preliminary report on the status of the new drug ephedrine

Handbuch der experimentellen Pharmakologie Herausgegeben von A Heffter, und W Heubner, Professor der Pharmakologie an der Universitat Gottingen III Band 1 Hälfte—Die osmotischen Wirkungen Schwer resorbierbare Stoffe, usw, usw Paper Price, 57 marks Pp 619, with 62 illustrations Berlin Julius Springer, 1927.

Any one who has seen and used the previously issued instalments (volumes 1 and 2) of this great work on pharmacology will welcome the present first half of the third volume The publication of this handbook, begun about fifteen years ago, has encountered a number of misfortunes. The World War broke out just as the first manuscripts were received, so that it was not until 1919 that the first half of the first volume could be published The recent death of Arthur Heffter, the originator of the ambitious plan, to publish as thorough and systematic a complete exposition as possible of all the work done on experimental pharmacology, was another heavy blow to the enterprise, fortunately met by the election of Wolfgang Heubner to the important position of editor-in-chief. The present instalment includes a presentation of the pharmacology of inorganic substances, excepting the heavy metals, which are to be taken up in the final instalment, to be published shortly.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender Selections will be made for more extensive review in the interests of our readers and as space permits Books listed in this department are not available for lending Any information concerning them will be supplied on request

Practical Methods in the Diagnosis and Treatment of Venereal Diseases for Medical Practitioners and Students By David Lees, D S O M A, M B, Surgeon in Charge of Venereal Diseases, The Royal Infirmary, Edinburgh With an introduction by Wm Robertson, M D, F R C P, D P H, Medical Officer of Health, Edinburgh Cloth Price, $5 Pp 605, with 87 illustrations New York William Wood & Company, 1927

Brief practical guide to the care of venereal disease

The Home Nurse's Handbook of Practical Nursing A Manual for Use in Home Nursing Classes in Young Women's Christian Associations in Schools for Girls and Young Women and a Working Text Book for Mothers, "Practical Nurses Trained Attendants, and All Who Have the Responsibility of the Home Care of the Sick By Charlotte A Aikens, R N Fourth edition Cloth Price, $2 net Pp 326, with illustrations *Philadelphia W B* Saunders Company, 1927

Thousands of details of nursing procedure

Birth Injuries of the Central Nervous System Part I—Cerebral Birth Injuries By Frank R Ford Johns Hopkins Hospital Part II—Cord Birth Injuries By Bronson Crothers and Marian C Putnam, Harvard Medical School Medicine Monographs Volume XI Cloth Price, $4 Pp 164, with 56 illustrations Baltimore Williams & Wilkins Company, 1927

Monograph showing how wrong traction during forcible delivery produces permanent injury

The Normal Chest of the Adult and the Child, Including Applied Anatomy, Applied Physiology, X Ray and Physical Findings By J A Myers Associate Professor of Preventive Medicine, Medical and Graduate Schools University of Minnesota and Others With an introduction by Elias P Lyon Cloth Price, $5 Pp 419, with 141 illustrations Baltimore Williams & Wilkins Company, 1927

Accumulation of fundamental data relating to the normal human chest

Nutrition of Mother and Child By C Ulysses Moore, M D, M Sc, F A C P, Collin's Fellow in Nutritional Research, University of Oregon Medical School Including Menus and Recipes by Myrtle Josephine Ferguson, B S, B S in H Ec Third edition Cloth Price, $2 Pp 236, with 33 illustrations Philadelphia J B Lippincott Company, 1927

Simple presentation of elementary facts for infant feeding

Chemical Laboratory Manual Prepared to Accompany Bogert's "Fundamentals of Chemistry" A Text Book for Nurses and Other Students of Applied Science By L Jean Bogert, Ph D, Research Chemist Obstetrical Department, Henry Ford Hospital Cloth Price, $1 50 net Pp 142, with 23 illustrations Philadelphia W B Saunders Company, 1927

Elementary guide to simple chemical experiments

The Pathological Findings in Four Autopsied Cases of Acromegaly, with a Discussion of Their Significance By Harvey Cushing, and Leo M Davidoff Monographs of the Rockefeller Institute for Medical Research No 22 Paper, $2 Pp 131, with 104 illustrations New York Rockefeller Institute for Medical Research, 1927

Monograph concluding that anterior pituitary lobe is key of the endocrine arch

Die Neurosen des Kindesalters mit besonderer Berucksichtigung von Lebensschwäche und Schwererziehbarkeit Von Dr W Cimbal, Oberarzt am Stadtkrankenhaus in Altona Paper Price 15 marks Pp 509, with 24 illustrations Berlin Urban & Schwarzenberg, 1927

Neuroses of children with special reference to the "difficult child"

Spirochaetal Jaundice By G Buchanan, M D, Ch B, D P H Medical Research Council Special Report Series, No 113 Paper Price, 4s net Pp 64 with illustrations London His Majesty's Stationery Office, 1927

Complete monographic study with good bibliography of recent investigations of this specific spirochetal disease

Fish and Sea Food Recipes Covering the Entire Industry Boards Price, 10 cents Pp 96 New York United States Fisheries Association, 1927

Management of the Sick Infant. By Langley Porter, B.S., M.D., M.R.C.S., Professor of Clinical Pediatrics, University of California Medical School, and William E. Carter, M.D., Instructor in Pediatrics, University of California Medical School. Third edition. Cloth. Price, $8.50. Pp. 726. St. Louis: C. V. Mosby Company, 1927.

New edition with few important revisions.

The Heart and Its Diseases. A Handbook for Students and Practitioners. By Charles W. Chapman, M.D., M.R.C.P., Consulting Physician to the National Hospital for Diseases of the Heart, London. Cloth. Price, $3.50. Pp. 216, with 52 illustrations. New York: William Wood & Company, 1927.

Outline of care of cardiac disorders.

Hygiene and Sanitation. The Essentials of Modern Health Care. By Jesse Feiring Williams, M.D., Professor of Physical Education, Teachers College, Columbia University. Cloth. Price, $2 net. Pp. 344, with 52 illustrations. Philadelphia: W. B. Saunders Company, 1927.

Practical guide to health care of the individual, the city and the nation.

An Introduction to Neurology. By C. Judson Herrick, Professor of Neurology in the University of Chicago. Fourth edition. Cloth. Price, $2.75 net. Pp. 406, with 140 illustrations. Philadelphia: W. B. Saunders Company, 1927.

New edition of well established guide to neurologic anatomy.

Exploration clinique et diagnostic chirurgical. Par Félix Lejars, professeur de clinique chirurgicale à la faculté de médecine de Paris. Second edition. Cloth. Price, 120 francs. Pp. 911, with 1094 illustrations. Paris: Masson & Cie, 1927.

New edition of well known guide to French surgical practice.

Tiger Trails in Southern Asia. By Richard L. Sutton, M.D., Sc.D., LL.D., Professor of Dermatology, University of Kansas. Cloth. Price, $2.25. Pp. 207, with 115 illustrations. St. Louis: C. V. Mosby Company, 1926.

Handsome account of a dermatologist's pursuit of unusual skins.

The Wistar Institute Bibliographic Service. Volume III. Issued by the Wistar Institute of Anatomy and Biology. Paper. Price, $5. Pp. 323. Philadelphia: Wistar Institute, 1927.

References and abstracts of all articles appearing in nine Wistar Institute publications.

An Outline of Careers. *A Practical Guide to Achievement.* By Thirty-Eight Eminent Americans. Edited by Edward L. Bernays. Cloth. Price, $5 net. Pp. 431. New York: George H. Doran Company, 1927.

Discussion of requirements, opportunities and pitfalls of various professions.

Modern Methods in Nursing. By Georgiana J. Sanders. Fourth edition. Cloth. Price, $3 net. Pp. 854, with 216 illustrations. Philadelphia: W. B. Saunders Company, 1927.

Elements of nursing knowledge well assembled and thoroughly indexed.

Social Factors in Medical Progress. By Bernhard J. Stern, Ph.D. Cloth. Price, $2.25. Pp. 136. New York: Columbia University Press, 1927.

Interesting study of factors encouraging and delaying medical progress.

Biology, General and Medical. By Joseph McFarland, M.D., Sc.D., Professor of Pathology in the University of Pennsylvania. Fifth edition. Cloth. Price, $2.50 net. Pp. 475, with 151 illustrations. Philadelphia: W. B. Saunders Company, 1927.

New edition of standard guide to human biology.

Nurses and Nursing. By Alfred Worcester, A.M., M.D., Professor of Hygiene in Harvard University. Cloth. Price, $2. Pp. 173. Cambridge: Harvard University Press, 1927.

Reprint of idealistic essays on the nursing profession.

The First Estate. By Charles A. L. Reed. Cloth. Price, $2.50. Pp. 530. Boston: Stratford Company, 1927.

Every doctor has one novel in his system—this one is Dr. Reed's.

A Text-Book of Medicine. By American Authors. Edited by Russell L. Cecil, A.B., M.D., Assistant Professor of Clinical Medicine in Cornell University, and Foster Kennedy, M.D., F.R.S.E., Professor of Neurology in Cornell University. Cloth. Price, $9 net. Pp. 1500, with 29 illustrations. Philadelphia: W. B. Saunders Company, 1927.

Miscellany

HOSPITAL SERVICE IN DENMARK

The whole public health movement in Denmark has been centered around the practice of medicine and particularly around the hospital service. So far as the writer is aware [says Thomas Parran, Jr., *Pub. Health Rep.*, May 27] there is no country in which the hospital service has been more fully developed, whether viewed from the standpoint of type of buildings and equipment, quality of the service rendered to the average citizen, extent to which hospitals are used, or cost of the service to the patient. Practically all the general hospitals in Denmark are public institutions constructed by the municipalities or counties, or jointly by the two. The hospitals are well distributed over the country. Practically all of them are general hospitals in the truest sense, having special wards or buildings for the diagnosis or treatment of tuberculosis, for the treatment of epidemic and venereal diseases, and for the temporary hospitalization of mental cases. The closed staff principle is universal, and the hospital physicians live on the hospital grounds. When a case is sent to a hospital, the attending physician loses all responsibility for the patient. The municipal hospitals are under the direction of a special branch of the municipal government; those operated jointly by a city or county are jointly administered. The director, i. e., the head physician (or physicians) is usually employed on a part-time basis, being allowed to supplement his salary by private consultations at the hospital. An opportunity was afforded the writer to visit a number of the hospitals. One of the most interesting was the state hospital in Copenhagen, operated by the department of education primarily as a teaching center for the university medical school. The director of each department is ex officio professor in the university. This institution has accommodations for 1,000 patients; it was completed in 1910 at a cost of $2,000 per bed. Fifty-three per cent of the patients pay only 50 cents a day, and 20 per cent of them pay nothing. The operating cost is about $3.50 per patient daily, of which 16 per cent is paid by patient's fees. The training school for midwives is operated as a part of this hospital, and there is a large nursing school. The city of Copenhagen expends nearly $4,000,000 a year for its general, tuberculosis and insane hospital services, representing an annual per capita expenditure of approximately $6. The average cost per patient daily is slightly over $3, and this average cost seems to prevail generally throughout the country. The cost of hospital construction in Denmark is nearly as high as that in the United States. The buildings are of a very permanent nature and are well equipped as regards furniture, laboratory, roentgen-ray, hydrotherapy, heliotherapy, and physical therapy departments. Private rooms comprise only 10 per cent of the whole hospital capacity, the favorite arrangement being a system of four or six bed wards, in which adequate floor and air space is provided. Every county has one or more large central hospitals and several smaller ones. In all there are 175 general hospitals with more than 14,000 beds, or 4.5 beds per thousand inhabitants. This compares with 2.6 general hospital beds per thousand in the United States. The number of patient days amounts to 4,300,000, or 1.4 days in general hospitals for every inhabitant annually, as compared with 0.61 patient days in the United States. In comparing the hospital facilities of Denmark and this country it should be noted that Denmark has 4.5 and the United States 2.6 general hospital beds per thousand inhabitants, and that in Denmark these beds are 87 per cent and in the United States 67 per cent occupied. The number of beds per capita for mental and nervous cases is approximately the same in the two countries. The number of beds for tuberculosis cases in Denmark is 1.1 per thousand inhabitants, and in the United States 0.44. The number of beds in all types of hospitals is for Denmark 8.5 per thousand inhabitants, and for the United States 7.1. The figure for the United States, however, includes 1.0 bed per thousand in institutions, such as old age homes, while this class of hospital bed is not included in the Danish statistics.

Application of Privileged Communications Statute

(New Orleans & N E R Co v Jackson (Miss), 110 So R 586)

The Supreme Court of Mississippi, division B, says that two trials were had of this action brought under the federal employers' liability act to recover damages for personal injuries On the last trial the only question to be determined by the jury was the extent of plaintiff Jackson's injuries and the amount of damages he was entitled to for such injuries Three physicians examined him to ascertain the extent of his injuries Two of them were introduced as witnesses in his behalf The other physician was offered by the defendant railroad company as a witness, but on objection of the plaintiff, was not permitted by the court to testify His testimony was material If allowed by the court it would have tended strongly to show that the plaintiff was not injured to the extent claimed by him and to the extent testified to by the two physicians who were permitted by the court to testify in his behalf The privileged communications statute of Mississippi (section 3695 code of 1906) provides, in substance, that all communications made to a physician or surgeon by a patient under his charge, or by one seeking professional advice, shall be privileged, and such physician or surgeon shall not be required to disclose them in any legal proceeding except at the instance of the patient The defendant contended that the statute, as applied in this case, had the effect of being more than a mere rule of evidence, that it affected the substantial rights of the defendant that it denied the defendant a hearing of its cause on its merits, that, so applied, the defendant was denied a right to which it was entitled under the federal employers' liability act and the applicable principles of the common law as interpreted by the federal courts But as this court views it, the privileged communications statute did not affect the substantive rights and obligations of the parties It is a statute affecting alone the competence of certain witnesses, is a mere rule of evidence, and so is applicable in an action under the federal employers' liability act

Action for Malpractice Barred by Defense to Bill

(Leslie v Mollica (Mich) 211 N W R 267)

The Supreme Court of Michigan, in affirming a judgment for the defendant physician in this action to recover damages for alleged malpractice in treating the plaintiff's fractured arm says that the judgment affirmed was rendered for the defendant on the ground that the plaintiff, when sued in a justice's court by the physician for medical services, made malpractice a defense and thereby defeated the physician's action for services When this action for malpractice was instituted the defendant contended that the plaintiff's use in the justice's court of his claim for malpractice exhausted his remedy for such injury, and it could not be made the basis of this action, while the plaintiff contended that section 12765 of the compiled laws of Michigan of 1915 sustained his right to plead malpractice by the defendant in defense of the suit in the justice's court, and on defeat of the defendant's action there for services, to bring this action for malpractice The statute mentioned provides that

> If any person professing or holding himself out to be a physician or surgeon shall be guilty of any malpractice, an action on the case may be maintained against such person so professing and the rules of common law applicable to such actions against licensed physicians and surgeons shall be applicable to such actions on the case, and such malpractice may be given in evidence, in bar of any action for services rendered by such person so professing

The purpose of this statute is apparent, it is aimed at empirics, and holds all such to the same accountability for malpractice as licensed physicians and surgeons This statute does not change, or attempt to change or enlarge, the common-law accountability of physicians and surgeons for malpractice An examination of the legislative history of the statute discloses that, from its inception in 1838, it was intended to apply to *any person not licensed as a physician* or surgeon but professing or holding himself out to be a physician or surgeon The defendant in the instant case was a licensed physician and surgeon, and the statute mentioned had nothing to do with the case

The suit in the justice's court, by the physician for his services, did not draw in issue, by its own force, the patient's independent cause of action for malpractice It was optional with the patient to make malpractice of the physician an issue in that suit, either to defeat recovery for services or to have damages awarded by way of recoupment or counterclaim, but this involved the hazard of losing all other remedy It is true that respectable authority is found holding that a recovery for services by the physician bars an action for malpractice by the patient, and, in jurisdictions where such rule prevails, the patient, when sued, is in quite a dilemma, for, if he does not defeat the action for services, the judgment for services is res judicata (an adjudication) that there was no malpractice Few cases, however, adopt such rule In some jurisdictions the rule only applies in case the patient appears and defends The better view, this court thinks, is that the actions, one by the physician for service and the other by the patient for malpractice, are *independent and remain so unless and until the patient, when* sued for services, injects the issue of malpractice, either to defeat the claim or to obtain damages by way of recoupment or counter claim The plaintiff's action for malpractice was indivisible, could not be split, and was employed in the justice's court as an affirmative defense and later as a foundation for this action

This court does not adopt the rule requiring the patient to make the defense of malpractice in the justice's court when sued by the physician for services He may do so, however This court is committed to the doctrine that an independent right of action in behalf of one sued may be put in issue or withheld at the option of the defendant But the plaintiff, although not required to make the defense of malpractice in the suit in the justice's court, elected to do so, and thereby visited on himself the legal consequences resulting The record did not disclose whether damages for malpractice were sought in the suit in the justice's court, but that was immaterial, as it was manifest that malpractice by the physician was alleged and employed as an affirmative defense, and defeated the physician's claim for services This court is constrained to hold that the plaintiff's use of his right of action for malpractice in defense of the defendant's claim for services in the suit in the justice's court barred this action

Permissible Exclusion from Practicing in Hospital

(Hayman v City of Galveston et al (U S), 47 Sup Ct R 363)

The Supreme Court of the United States, in affirming a judgment dismissing appellant Hayman's bill in which he asked for an injunction against the enforcement of any rule or regulation excluding him or other osteopathic physicians from practicing their profession in the John Sealy Hospital, maintained by the city of Galveston, and denying admission to patients who wished to be treated by him or other osteopathic physicians, says that the bill alleged that the state of Texas, acting through the board of regents of the state university, had leased to the city the land on which it was maintaining the hospital The lease stated that the state reserved the right of use of the operating amphitheater, the wards and grounds of the hospital by the faculty of the medical department of the state university, for purposes of clinical instruction of students attending the university in Galveston, and reserved also the right for such purposes to control the treatment of all charity patients

The appellant argued that the state constitution and laws conferred on him the asserted right which was infringed by the action of the hospital board But if it be assumed that the question presented was the same as though the state legislature had enacted the regulation adopted by the hospital board, the appellant failed to suggest, and the supreme court fails to perceive, any substantial basis for asserting that rights guaranteed to him by the fourteenth amendment to the constitution of the United States had been infringed The *only protection claimed here was that of the appellant's* privilege to practice his calling. However extensive that protection might be in other situations, it cannot, the supreme court thinks, be said that all licensed physicians have a constitutional right to practice their profession in a hospital maintained by a state or a political subdivision, the use of which is reserved for purposes of medical instruction. It is not incumbent on the state to maintain a hospital for the private practice of medicine.

But it was argued that, if some physicians were admitted to practice in the hospital, all must be, or there is a denial of the equal protection of the laws. Even assuming that the arbitrary exclusion of some physicians would have that legal consequence in the circumstances of this case, the selection complained of was based on a classification not arbitrary or unreasonable on its face. Under the Texas constitution and statutes any one who shall "offer to treat any disease or disorder, mental or physical, or any physical deformity or injury by any system or method, or to effect cures thereof" is a physician and may be admitted to practice within the state. This court cannot say that a regulation excluding from the conduct of a hospital the devotees of some of the numerous systems or methods of treating diseases authorized to practice in Texas is unreasonable or arbitrary. In the management of a hospital, quite apart from its use for educational purposes, some choice in methods of treatment would seem inevitable, and a selection based on a classification having some basis in the exercise of the judgment of the state board whose action is challenged is not a denial of the equal protection of the laws.

The validity of the action of the board under the Texas constitution was also before the court. Article 16, section 31, of the Texas constitution provides that:

> The legislature may pass laws prescribing the qualifications of practitioners of medicine in this state, and to punish persons for malpractice, but no preference shall ever be given by law to any schools of medicine.

The limitation of the provision is obviously directed to the qualifications of those to be admitted to the practice of their profession in the state, and has nothing to do with the qualifications of those who are to be allowed to practice in a state hospital or to participate in an educational enterprise conducted by the state. The action of the board of managers of the hospital, which it was alleged had made regulations excluding the appellant and other licensed osteopathic physicians from practicing in the hospital and excluding patients who desired to be treated by the appellant or other osteopaths, did not violate rights or immunities guaranteed by either the state or the federal constitution.

Physician Not Liable for Labor Pains

(Adkins v. May (Ky.), 288 S. W. R. 735)

The Court of Appeals of Kentucky, in reversing a judgment for $200 damages that was rendered in favor of the plaintiff, Mrs. May, for alleged malpractice, says that it appeared that when the defendant was called he went to the plaintiff's home with a trained nurse. He found that the plaintiff had had an incomplete miscarriage, and that there was a considerable hemorrhage. Being unable to remove the remainder of the fetus, he packed the womb with gauze in order to stay the hemorrhage and bring on labor pains, telling the plaintiff and those at her bedside to leave the packing there and he would return. The patient and a woman with her said that the defendant told her that the child was born and that she was all right, while he denied that he made such statement. All the physicians who testified in the case said that the method of treatment adopted was proper. After the defendant left, the plaintiff's labor pains came on sooner than was expected, and the remainder of the fetus came out. The plaintiff's husband said that he would get another physician. While going for one, he met the defendant, told him of the situation, and the defendant said that he would go to the plaintiff's home. Thereupon the husband said that he was going to get another physician.

There was no evidence that the method of treatment was improper, although there was some evidence to the effect that if a physician had been present when the labor pains came on he might have lessened the plaintiff's suffering. But the physicians all agreed that in the circumstances it was not improper for the defendant to leave for a short period of time to go to his office, where he could readily be reached in case of emergency. That being true, the plaintiff's case turned on whether the defendant's alleged statement that the child had been born was actionable negligence. As the defendant packed the womb for the purpose of bringing on labor pains and causing the fetus to be discharged, it was highly improbable that he stated that the child had been born; but, assuming, as this court must in view of the evidence, that this statement was made, the question was, was it such negligence as to authorize a recovery? The plaintiff's insistence was that if she had known that the child had not been born she would have secured the services of another physician, but whether in view of the fact that she already had a physician employed she would or could have secured the services of another physician in time to lessen her suffering was a matter of pure speculation. In other words, the case was one in which it was so highly probable that the plaintiff would have undergone the same labor pains had the alleged false statement not been made, and so highly improbable that the alleged false statement added to or contributed to her suffering in any way as to make the question a matter of guess work, and therefore such as should not have been submitted to the jury. It followed that the defendant's motion for a peremptory instruction should have been sustained.

Inference from Not Calling Physicians as Witnesses

(Nelson et al. v. Public Service Trans. Co. et al (N. J.), 135 Atl. R. 467)

The Supreme Court of New Jersey says that this action was instituted by Mrs. Nelson and her husband to recover damages arising from an injury alleged to have been received by her when a passenger in a bus of the company. After the accident she was treated by two physicians. She complained of an injury to her arm, which prevented her from keeping boarders. So far as damages were concerned, the plaintiffs relied on their own testimony. The two physicians were not called by them as witnesses. The defendants called two physicians, who testified that they had examined Mrs. Nelson. One of them testified that his examination was made eleven or twelve days after the accident, and the only objective condition she had was a slight discoloration of the right arm. The other symptoms were subjective. The other physician made his examination between six and seven months after the accident, and testified that he did not find anything to indicate any physical injury or any organic or nervous condition. The jury returned a verdict in favor of Mrs. Nelson for $75 and for Mr. Nelson of $25. The court cannot say that the amounts of the verdicts were not supported by the testimony, or that they showed any passion or prejudice on the part of the jury against the plaintiffs. The plaintiffs did not call the physicians who had attended Mrs. Nelson immediately after the accident. The jury had the right to infer that they were not called because, if called, they would not testify favorably to the plaintiffs on the subject of Mrs. Nelson's injury.

Privilege Not Waived by Introducing Proofs of Death

(Acee v. Metropolitan Life Ins. Co. (N. Y.), 219 N. Y. Supp. 152)

The Supreme Court of New York, appellate division, fourth department, says that at the trial of this action to recover on a life insurance policy the defendant was permitted to introduce the testimony of physicians who had attended the insured. They testified that she was suffering from heart and kidney disease long before and at the time the policy was issued. The testimony was received over the objection of the plaintiff that it was incompetent, and that the witnesses were incompetent under section 352 of the civil practice act of the state, which provides that a physician "shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity." That the testimony was improperly received, unless the statutory provision was waived, is established beyond question. But it was urged that the plaintiff had waived the provisions of section 352 and made the testimony competent by introducing in evidence the proofs of death which were served on the defendant, particularly in view of the fact that the policy contained a provision that "proof of death shall be evidence of the facts therein stated in behalf of, but not against the company" The policy also provided that "proofs of death shall be made on blanks to be furnished by the company and shall contain answers to each question propounded to the claimant, physicians and other persons" The attending physician answered the questions on the printed form, and the plaintiff, in establishing his case, introduced the proofs of death in evidence The defendant insisted that the introduction of the proofs of death in evidence opened the door for it to call other physicians to testify to what they discovered while treating the insured in a professional capacity but the court holds otherwise—that the introduction of the proofs of death did not have the effect of waiving the privilege Under section 836 of the code of civil procedure as amended in 1891 and section 354 of the civil practice act the only one who can waive the privilege is the personal representative, and it can only be waived on the trial when the evidence is offered

Validity of Will of Person Mentally Weak—Insanity

(In re Sexton's Estate (Calif) 251 Pac R 778)

The Supreme Court of California, in reversing an order which granted a new trial after a verdict upholding the will contested in this case says that this was a case of a loss of mental power, not one of an irregular working of the mental faculties, but of a ceasing to work with normal strength It was the contestant's theory at the trial that the mental processes of the testatrix were so benumbed by paralytic strokes that her mind was not strong and clear enough to make a valid disposition of her property by will A careful consideration of the testimony of the contestant's witnesses left in the mind the composite mental picture of a woman 61 years of age at the date of the execution of the will, grown old before her time feeble in body mentally weak, and given to an habitual quiescence and a torpor peculiar to those who have suffered from cerebral hemorrhage While a survey of all the facts might warrant a diversity of opinion as to the exact state of her mind and the precise degree of mental capacity retained by her, it was evident that there was not such a complete prostration or alienation of intellect as to incapacitate her from making a testamentary disposition of her property According to the testimony of the proponents' witnesses, uncontradicted by any direct evidence to the contrary, the plan of the will was the product of the testatrix's own mind, uninfluenced by the advice or dictation of any other The mind that so planned must have had testamentary capacity

A testator is of sound and disposing mind and memory if, at the time of making his will, he has sufficient mental capacity to be able to understand the nature of the act he is doing, to understand and recollect the nature and situation of his property, and to remember and understand his relations to the persons who have claims on his bounty and whose interests are affected by the provisions of the instrument The actual mental condition of the testator at the time of the execution of the will is the question to be determined Evidence as to mental condition before and after the execution of the will may be relevant and admissible, but it is important only so far as it tends to show mental condition at the time of executing the testamentary document That is to say, facts as to mental condition, whether anterior or subsequent to the date of the execution, depend for their probative force on the clearness and certainty with which they tend to demonstrate the condition of mind and memory at the moment the will was executed Evidence of mental condition before or after the execution of the will, if it has evidentiary force, i e, if there exists a reasonable and logical relation between it and the issue as to mental competence at the moment of execution, is to be given such weight as the jury thinks it deserves

"Insanity" is a broad, comprehensive and generic term of ambiguous import In a medical sense, it is used to denote any unsound and deranged conditions of the mind, and every degree of mental unsoundness, whatever may be its source or cause But mere proof of mental derangement, or of insanity in a medical sense, is not sufficient to invalidate a will Not every degree of mental unsoundness or mental weakness will suffice to destroy testamentary capacity The contestant is required to go further than that He must either show such a complete mental derangement as denotes utter incapacity to know and to understand those things which a testator must be able to know and to understand in order to possess testamentary capacity, or he must show the existence of a specific insane delusion which affected the making of the will in question In other words, mental derangement sufficient to invalidate a will must be an unsoundness of mind in one of two forms (1) mental unsoundness of such broad character as to establish incompetence generally, or (2) some specific and narrower form of insanity under which the testator is the victim of some hallucination or delusion And, even in the latter class of cases, it is not sufficient merely to establish that the testator was the victim of some hallucination or delusion, it must be shown that the will was the offspring of the hallucination or delusion

Testamentary capacity is always presumed to exist until the contrary is established Ability to transact important business, or even ordinary business, is not the legal standard of testamentary capacity A person who has mental power to understand and to transact the ordinary business affairs of life, doubtless, has capacity to make a valid will But the converse is not necessarily true Mental perception and power to think and reason of a lesser degree than that which is required in the understanding and transaction of ordinary business may be all that is requisite to the full understanding of everything involved in the execution of a will

The Family Physician—Admissibility of Testimony

(Turner v Stoker (Texas), 289 S W R 190)

The Court of Civil Appeals of Texas, in reversing a judgment for $1,250 damages rendered in favor of plaintiff Stoker for alleged malpractice by the defendant, says that it does not understand that in order for a physician to testify as an expert in a malpractice case it is necessary for him to practice or live in the same community as the defendant, but if the witness is qualified to testify as to the practice in the same or similar communities he is qualified to give an expert opinion As this court views it, a physician may practice his profession in some one of the larger cities of the state and yet be sufficiently familiar and acquainted with the practice of the profession in the villages to qualify him to testify If the rule went so far as to require that a physician before being permitted to testify must practice in similar communities the complaining party in an action for malpractice might be absolutely helpless Of course the court understands that the physician practicing in a village and in small communities does not have the opportunities and resources to give the same treatment and diagnosis as what may be called the city physician The village physician must observe his patient by candle and lamp light, he does not have the advantage of the roentgen ray and other instrumentalities that are afforded in the great cities with sanatoriums; and of course the same treatment and degree of care would not be applied to a physician practicing in such a community as to one practicing in a city

The family physician is one of the most confidential persons the public has to deal with His responsibility is that of one of the greatest of professions When we are sick or injured, we place our life in his hands, and his advice and treatment may mean life or death It is quite natural that he should be required to exercise that degree of skill, learning and care which are ordinarily possessed and exercised by other such members of his profession in good standing practicing in similar communities and under like or similar circumstances He is not chargeable with negligence or failure to use his best skill and ability, but only that care and skill exercised generally by physicians in the same or similar communities The physician is not an insurer and does not warrant a cure, but he impliedly contracts that he possesses, and he is required to exercise, that degree of skill and care which physicians practicing in similar locations ordinarily possess He does not impliedly warrant a cure, and can be held as a guarantor only by virtue of an express agreement

The testimony showed that the defendant was called after an accident to attend the plaintiff, that the only thing he prescribed was "mentholatum and let nature take its course." He assured the plaintiff that there were no broken bones, and when the plaintiff paid $50 for his services, admitted that the jaw was broken. While the defendant was not bound to diagnose carefully, or know, that which could not be seen, for many of our ailments are hidden, yet the fact that he did not advise a roentgenogram, did not discover the broken jawbone, and was guilty of other failures as detailed by the witness was sufficient for the jury to conclude that he was negligent. There is no profession that has advanced further than the medical. Too much cannot be said of the wonderful achievement of medical science. The advance in the treatment and cure of ailments seems also miraculous. It is no wonder, then, the confidence and faith of a people in the physician, and it is but reasonable that they should receive that treatment afforded in the same or like communities.

This court does not understand that the law of Texas recognizes or makes any distinction between physicians admitted and licensed to practice the profession in Texas, as a test of qualification to testify as experts.

But the trial court's omission from its charge on proximate cause of the doctrine "that foreseeableness or anticipating of injury is a necessary element of proximate cause" was such a fatal omission as required a reversal of this cause, which was therefore reversed and remanded. In *T. & P. R. Co.* v. *Bingham*, 90 Texas 223, 38 S. W. 162, the Supreme Court of Texas quoted the following as a correct statement of the doctrine:

> In order to warrant a finding that negligence or an act not amounting to wanton wrong is the proximate cause of an injury, it must appear that the injury was the natural and probable consequence of the negligence or wrongful act, and that it ought to have been foreseen in the light of the attending circumstances.

Truth-Telling Serum Claptrap

(State v. Hudson (Mo.), 289 S. W. R. 920)

The Supreme Court of Missouri, division 2, in affirming a conviction of the defendant, a negro, of rape on an elderly white woman, says that it was sought to introduce in evidence the deposition of a "doctor" residing elsewhere, who testified to the effect that he had administered to the defendant what he termed a "truth-telling serum," and that while under its influence the defendant had denied his guilt. Testimony of this character—barring the sufficient fact that it cannot be otherwise classified than as a self-serving declaration—is, in the present state of human knowledge, unworthy of serious consideration. This court was not told from what well this serum was drawn or in what alembic its alleged truth-compelling powers were distilled. Its origin was as nebulous as its effect was uncertain. A belief in its potency, if it has any existence, is confined to the modern Cagliostros, who still, as Balsamo did of old, cozen the credulous for a quid pro quo, by inducing them to believe in the magic powers of philters, potions, and cures by faith. The trial court therefore, whether it assigned a reason for its action or not, ruled correctly in excluding this claptrap from the consideration of the jury. Cogent reasons based on numerous rulings bear ample testimony to support the wisdom of the court's ruling.

Right to Call Investigating Physician as Witness

(Osborn v. City of Seattle (Wash.), 252 Pac. R. 164)

The Supreme Court of Washington says that three actions which arose out of a collision between an automobile and a street car owned and operated by the defendant were consolidated for trial. The defendant through its claim department caused a physician to examine the injured plaintiffs and make a report thereof. This examination was made with the consent of the persons examined. On the trial the plaintiffs called the physician for the purpose of having him testify as to the examinations he had made. The defendant contended that these examinations were a part of the investigation of the claim and of the preparation for the trial of the case, and the information obtained was confidential. But no case was cited, and this court does not know of any authority which would sustain a holding that a person who voluntarily submits to an examination by a physician, even though the examination was made at the instance of the adverse party, may not call that physician as a witness on the trial and interrogate him relative to the examination. This case was entirely different from that of seeking by interrogatories to get possession of the report which the physician may have made to the person employing him. When the plaintiffs voluntarily submitted to the examination, it naturally would be on the implied assumption that they might call the physician as a witness on the trial if they saw fit to do so. To suppress such evidence in many cases would keep out of the trial facts which the court or the jury should know in order that a just determination of the cause might be had. Reason at least supported the right of the plaintiffs to call the physician in the present case and take his testimony relative to the examinations which he made.

Society Proceedings

COMING MEETINGS

Colorado State Medical Society, Glenwood Springs, September 6-8. Dr. F. B. Stephenson, Metropolitan Building, Denver, Secretary.
Idaho State Medical Association, Twin Falls, August 29-31. Dr. J. N. Davis, Kimberly, Secretary.
Oregon State Medical Society, Salem, September 1-3. Dr. F. D. Stricker, Medical Arts Building, Portland, Secretary.
Washington State Medical Association, Tacoma, August 29-31. Dr. C. H. Thomson, 508 Cobb Building, Seattle, Secretary.

MEDICAL ASSOCIATION OF GEORGIA

Seventy-Eighth Annual Meeting, held at Athens, May 10-13, 1927

The President, Dr. V. O. Harvard, Arabi, in the Chair

The Newer Psychology in Its Practical Application to General Medicine

Dr. W. W. Young, Atlanta: If we conceive of the "mind" as an expression of the entire organism, psychology has a very definite message to the man of medicine. First, it is the pediatrician or the family physician who comes in contact with the child and the young mother. It is their advice which is sought in all emergencies. It is within their scope to inculcate right principles of habit formation both in the emotional and in the psychic levels and thus prevent the growth of an organism poorly adapted to meet the stresses of life. It is also within the province of the family physician to eradicate sources of irritation to the autonomic and cortical systems. But, above all, the supreme note of caution should be sounded in the handling of the convalescent. In acute disorders, especially the acute infections, the sympathetic is in a state of constant activity, so that in the period of convalescence an autonomic imbalance with consequent emotional instability is to be expected. This means that emotional situations may have a more pronounced and perhaps disastrous effect on such an individual than ordinary. Incapacity for motor response with proper metabolism of the products of sympathetic physiologic response gives rise to by-products which are toxic. Therefore such a patient should be relieved of all stimuli that might so upset him. Odors, noises, apparently insignificant events may be the source of irritation and may be a tremendous factor in retarding recovery. Of course, major emotional stimulation may have a very pronounced result. The surgeon, too, may find sources or difficulty in improperly balanced individuals. The approach to a major operation should be fraught with as little emotional atmosphere as possible, if the best results are to be obtained. The convalescence should be guarded as carefully as in the case of an acute infection. Any individual who is sick has a fundamentally abnormal adaptive system and hence must have environmental factors controlled. The biologic conception shows us that the "mind" is not some mystical entity which may be dissected and controlled separate from the physical but is indivisible from the organic make-up of the individual: a dynamic expression of the organism's contacts. From this conception every man in the practice of medicine may draw lessons for his guidance in handling his every-day clientele.

Dried Yeast Therapy in Certain Psychoses

Dr. H. D. Allen, Milledgeville: Certain psychoses show marked improvement with increased body weight or improved nutrition, especially the toxic exhaustion types, whether from endogenous or from exogenous toxic causes. Skin eruptions characteristic of pellagra were apparently healed in three cases concomitant to an improvement in nutrition as recognized by prompt increase in body weight. Improvement in the mental state in these three cases was also noted. The improvement in nutrition in the ten cases reported here was very prompt and coincident to the addition of dried yeast (brewers') to the diet of these patients. The value of dried yeast as an addition to the food mixture for nasal tube feeding is suggested. Three cases of pellagra are presented as additional confirmation of the claims of a specific value of dried yeast in this disease.

Popular and Professional Misconceptions Regarding Malaria

Dr. M. A. Fort, Atlanta: Numerous people have told me about catching malaria from eating fish caught in stagnant ponds, chewing sugar cane, drinking bad water, eating rotten ended watermelons, green scum or drying up of ponds, night air, flies, etc. Some prominent physicians have assured me that mosquitoes raised in the vines about their porches cause it. I was asked to make an agricultural college quit raising cow peas because they bred mosquitoes. I have heard physicians advise their patients to put down deep wells, as the water from shallow wells produced malaria. Malaria is not caused by bad water, air or food. Nothing causes malaria but an animal being, having as definite a mode of existence as a boll weevil. This parasite is put in by a mosquito and by nothing else. It lives in only two places in the world: in the human blood and in the mosquito. It dies immediately if placed in water, so it cannot enter in the drinking water. It cannot live in any food, so it cannot be eaten. It cannot live in air, so it cannot be breathed in. One can get it only when an infected mosquito inserts her bill and spits. The only mosquito that can carry this parasite is the anophelene, and the only variety of anophelene to be feared in Georgia is *Anopheles quadrimaculatus.* The Quads develop only in ponds and not in running streams, tin cans, barrels, tubs, septic tanks, wells or other holes dug in the earth, as the borrow pits made in road building. The clean-up campaigns for removing cans and trash are good for comfort, but they have no influence in preventing malaria. The Quad prefers water in a limestone country, and the limestone areas and the malaria areas of the state are the same. A mosquito must be over 10 days old before she can transmit malaria. This is the basis of LePrince's excellent method of preventing malaria by destroying all the mosquitoes in the house daily. Malaria is not transmitted in the winter in Georgia, but the parasite lives in the blood of uncured persons all winter. If fever appears in a house in which Quad mosquitoes can be found hiding in the dark places in the daytime, or if the larvae of the Quad mosquito can be found in nearby ponds, it is strong presumptive evidence of malaria. If, in addition, there is a history of other cases of malaria and the presence of an enlarged spleen, the diagnosis is wellnigh absolute. When a stained blood smear is examined and the characteristic parasites are found we have one of the most satisfactory and absolute diagnoses known to medicine. If we depend on the microscope alone we shall miss malaria more than 90 per cent of the time.

Reducing Obstetric Mortality

Dr. Lewis H. Wright, Augusta: There are three main factors concerning the successful handling of an obstetric case: (1) faithful, thoughtful, intelligent prenatal care; (2) proper management during labor, and (3) careful postnatal care and follow-up. Not one of these factors may be neglected.

Banana Diet in the Treatment of Chronic Intestinal Indigestion in Children

Dr. Joseph Yampolsky, Atlanta: Bananas, when ripe, are very digestible. They were used in conjunction with protein milk and a regular course of intestinal elimination in three cases of severe celiac disease. The patients gained in weight and after two years of observation are apparently well.

Starvation Diet Versus Feeding in the Treatment of Summer Diarrheas

Dr. W. A. Mulherin, Augusta: The modern idea in the treatment of ileocolitis is the same in principle as the treatment of typhoid—support the baby's vital force with food of sufficient strength to be of some real value, until the infection has run its course. Treat symptoms as they arise, giving medicine only if there is a direct indication for it. Give plenty of water to drink; if necessary, force it, or give it artificially, in order to keep the tissues and organs of the body functioning in a normal manner, thereby preventing metabolic disturbances that frequently claim the life of the little patient.

Pigment Metabolism in the New-Born

Dr. M. Hines Roberts, Atlanta: Serum and spinal fluid of new-born infants contain protein-bound bilirubin, as shown by the indirect van den Bergh reaction, and hence the bilirubinemia is of the hemolytic type. The normal pigment concentration ratio of serum to spinal fluid is greater than 100:1. A serospinal fluid pigment ratio that is less than 50:1 indicates the presence of blood in the spinal fluid at some time. The threshold of clinical jaundice in the new-born is higher than that for the adult, apparently well above an icterus index of 40.

Zinc Stearate Poisoning

Dr. L. H. Goldsmith, Atlanta: Zinc stearate dusting powder has been used extensively as a substitute for talcum powder, although it has no advantage therapeutically and is more dangerous. The inhalation by infants has resulted in twenty-eight deaths (21 per cent) in 131 cases reported. One 3 months old infant died within one hour. Its use should be discouraged and mothers should be warned of its dangers by the medical profession.

Diagnosis of Syphilitic Bone Lesions

Dr. James J. Clark, Atlanta: The ease and accessibility of roentgen-ray examination make possible a safe and simple method of early, and often positive, discovery of this infection. This is particularly true in children, in whom frequently the factor of a possible hereditary infection is lost sight of and considerable time lost and expense incurred while attempting to treat the child for some other infection, when a careful survey of the osseous system will readily give a correct diagnosis and permit of proper treatment. In any case of bone infection of chronic nature, the addition of antisyphilitic treatment to other therapeutic and dietary measures is certainly to be recommended. The physician will many times be surprised and delighted at the prompt response the patient will show to this form of therapy.

Treatment of Superficial Malignant Lesions by Combined Methods

Dr. J. W. Landham, Atlanta: The best results will not be obtained in the treatment of malignant growths without resorting to a combination of methods. Frequently it is necessary to use all the available methods in order to accomplish a cure. All the lesions of the larynx, lip, tonsil, mouth, penis and pigmented lesions in my series have been treated by a combination of diathermy and irradiation. Mortality statistics of this series of malignancies were: face, 6⅔ per cent; lip, 16⅔ per cent; nose, 3$\frac{4}{7}$ per cent; pharynx, 66⅔ per cent; antrum, 33⅓ per cent; tongue, 66⅔ per cent; penis, 50 per cent; and mouth, 30 per cent. Good cosmetic results were obtained in all the other cases in this series. Much remains to be accomplished in the education of the public in reference to malignancy. This should be pushed relentlessly. Prophylactic measures should be in the minds of physicians at all times, and the patient should be advised accordingly. Biopsies are condemned. It is safer to overtreat superficial malignant tumors than to run the risk of undertreating them in an effort to obtain good cosmetic results.

The Necessity of Pyelograms in Urologic Diagnosis

Dr. Wallace L. Bazemore, Macon: The use of ordinary antiseptics without an attempt at localization of urinary infections is to be condemned. Urography is not without its dangers, and its routine employment is not advised. It should be used only when the clinical diagnosis cannot be made without it. Urography is contraindicated when the patient is of advanced age or greatly emaciated, in cases of advanced bilateral renal disease, and when it is apparent that surgical treatment will not be of benefit.

Injection of Uterus and Fallopian Tubes with Iodized Oil as Aid in Diagnosis

Drs. E. H. Greene and Robert C. Pendergrass, Atlanta: We have used this procedure in about fifty cases and in none have we seen any evidence of reaction or untoward effect, either immediately or subsequently. There is a suggestion of some therapeutic value to the injection, as three or four of the patients with chronic salpingitis have reported a noticeable improvement; i. e., feeling better, marked decrease of the leukorrheal discharge, and gain in weight.

Etiology of Urinary Infections

Dr. Earl H. Floyd, Atlanta: The determining factors in the etiology of these infections are: (1) the type of infection; (2) the manner in which it invades the urinary tract; (3) the sources, and (4) the condition of the tract that predisposed it to infection. A systemic outline should be followed in all cases. An extensive examination is not always necessary, but in obscure conditions one should not hesitate to use every available means in investigating the urologic tract from the external urethral orifice to the cortex of the kidney. A few pus cells, even in very small microscopic amount, are of significance, and a careful examination should be made to determine their source. The likely association between urinary infections and infections elsewhere in the body should always be borne in mind. An endeavor should be made to determine whether there is some mechanical obstruction present, for this is the most common etiologic factor in upper urinary tract infection.

Wassermann Test

Drs. Paul Eaton and F. L. Damren, Augusta: There is much room for increasing the usefulness of the Wassermann test by the wider dissemination of information concerning its true import. The 2,275 tests we analyze comprise a little more than half the work of our laboratory so far this year. In sixty-seven of these cases the blood serum was anticomplementary. We were able to check fifty-three of these cases with the Kahn test and found that it was positive in forty and negative in thirteen of them. The fourteen which we did not test amount to only 0.5 per cent. It must be constantly borne in mind that the test, while enormously valuable, is not infallible and that the responsibility for diagnosis falls, not on the laboratory, but on the physician. The physician must use the Wassermann test just as he would use a watch or a thermometer, with a full appreciation of its weaknesses and shortcomings.

Rat Bite Fever

Dr. R. S. Leadingham, Atlanta: Sodoku, or rat bite fever, is a disease transmitted by the bite of a rat carrying *Spirochaeta morsus-muris.* I have isolated the organism by animal inoculation from two of three cases observed in Georgia. Seventy-three rats caught in Atlanta and vicinity and examined were found not to harbor the parasite in their peripheral blood streams. Arsphenamine is a specific and rarely more than two small doses have been necessary to effect a cure.

Rôle of Plasma Chlorides in Lobar Pneumonia

Dr. John W. Daniel, Savannah: These are three conditions — saline contents, hydrogen ion concentration, and temperature — which are capable of altering the dissociation curve of hemoglobin. In pneumonia the physician must combat all three. The temperature may be controlled with baths, exposure to cold air, etc., but not with drugs. The low plasma chlorides and high hydrogen ion concentration may often be controlled by intramuscular injections of a normal or hypertonic salt solution. In a patient of average weight, whose heart is functioning fairly well and the volume of urine good, injections of 500 cc. of physiologic sodium chloride solution should be given every three hours. The quantity should be based on the amount of plasma chlorides. If the chlorides are very low, 200 or 300 cc. of hypertonic solution should be injected every three hours until the plasma chlorides are at least 500 mg. If laboratory facilities are not convenient, the appearance of chlorides in the urine is a fairly good guide for the discontinuance of the injections. For patients who are in coma or unable to retain food and are in need of nourishment and fluid in the tissues, 10 per cent dextrose should be added to the saline injections. The dextrose furnishes calories as well as glycogen, which is the best of all heart stimulants. The condition of patients with dilatation of the right ventricle may be improved by drawing 200 or 300 cc. of blood from a vein. These are the cases in which the hypertonic solutions should be used so as to avoid injecting a large volume of fluid. We have treated eight cases of lobar pneumonia as outlined. The treatment in each case was based on the laboratory reports. These patients recovered. We do not claim that the injection of salt solution is a panacea for pneumonia. The claim is made that when the chemical equation reaches the point of equilibrium the sodium is no longer available for buffering the hydrogen ion of carbonic acid. The injection of sodium chloride will furnish the base, sodium ion, and prevent the development of an acidosis which is usually fatal.

Otomycosis

Dr. Arthur G. Fort, Atlanta: Attention was called particularly to this condition as it affected the external auditory canal and drum membrane of a large number of people presenting themselves for treatment in south Florida, particularly during the six weeks following the hurricane ot Sept. 17 and 18, 1926. It was not unusual to see three or four new cases every day. The most common forms of fungi with which we came in contact were of the species *Aspergillus niger* and *fumigatus.* These were identified by the detritus in the ears and by the growths and smears confirmed by the laboratory study. The development of the spores in the external auditory canal is rapid, as there is warmth and moisture and they are protected from every mechanical interference. The growth is augmented or stimulated quite often by the instillation of oil, so often used to soothe discomfort in the ears. The diagnosis is easy if one is looking for fungus invasion, and it is to be differentiated from seborrheic dermatitis and eczema. Microscopic examination will definitely settle the matter. The prognosis is always favorable, even though the drum membrane has been penetrated, provided one has an appropriate treatment and seeks a dry climate. The ear should be thoroughly irrigated with warm water, thereby removing a large part of the growth and detritus. Hydrogen peroxide should be instilled and allowed to remain in the ear for a few moments; the ear should be irrigated with warm water; 10 per cent cocaine in 1:1,000 solution of epinephrine hydrochloride should be instilled and allowed to remain ten minutes; the ear should be dried and about ten drops of pure alcohol instilled. This should be repeated every day for a period of at least one week and then at intervals of one week for a month or more. Under this treatment our patients were relieved, and when they persisted in treatment relapses were rare. After the first two or three treatments all medications except alcohol can be omitted.

So-Called Irreducible Minimum in Surgical Mortality

Dr. C. W. Roberts, Atlanta: There must be a quickening of surgical conscience. Only a deep-rooted acceptance of responsibility for outcome in operative procedure can furnish the urge that is required to stand by threatening failure constantly with the optimism of hope and with maximum efficiency. There is no mortality rate in a given surgical condition that should be accepted as standard. Team work and cautiously adapted variations of procedure lower mortality rates. There must be an occasional stock taking among surgeons in order to see where emphasis is being placed and to find the motive that activates them. In the "poor surgical risk" group timely preparation, well chosen anesthesia, and proper and intelligent postoperative care overseen by experienced men who anticipate and properly meet threatening complications constitute the most fruitful measures of lowering prevailing death rate percentages. Cells die without water, and sugar furnishes the body's necessary fuel. They should be used. That personal or personally supervised care of patients yields a lower death rate may be attested by comparing mortality tables compiled by small clinics where authority is centralized and procedure standardized to those of large hospitals where there is a tendency to lose sight of the individual in a mad rush to serve large numbers. End-results should be more and more the yard stick by which a surgeon's work is measured.

Injection of Internal Hemorrhoids

Dr. M. C. Pruitt, Atlanta: The solution I use in the great majority of cases is phenol (carbolic acid), 1 drachm (4 cc.); glycerin, 3 drachms (12 cc.); water, 4 drachms (15 cc.), or a 12.5 per cent solution. The object of the injection treatment is to produce, by irritation, sufficient fibrosis to obliterate the network of dilated blood vessels forming the hemorrhoids, causing them to shrink and not sufficient to cause sloughing of tissue. The relief of symptoms after the first treatment by the injection method is so complete that it is frequently hard to get the patient to believe that he needs any further treatment. This increases the percentage of recurrences. It is absolutely essential to have sufficient knowledge of the anatomy of the part and to make a physical examination with such a degree of care to enable differentiation between external and internal hemorrhoids, as only the internal type without complications is suitable for this method. The injection method is not without fault, but must be recognized as one of the standard forms of treating internal hemorrhoids.

Periodic Examination of Apparently Healthy Persons

Dr. Edgar A. Hines, Seneca, S. C.: To promote the better equipment of South Carolina doctors not only to undertake examinations of the apparently healthy citizen but to give him the most scientific care when he is sick, the board of trustees of the State Medical College, April 28, 1927, on request of the state medical association, decided to open the doors of the college twice a year for intensive intramural postgraduate courses free of charge. In addition to this service, the entire faculty will also be available for twelve months out of the year to go out to the county and district medical societies and give brief intensive courses to the busy practitioners who cannot leave their homes. These professors will be prepared to instruct physicians in the latest methods of conducting health examinations, in addition to other courses as desired. The basic idea of the leaders of the American profession is that these health examinations shall be made by the private practitioners rather than in a wholesale manner by health clinics of the commercial type. The practitioner is competent, though in many instances it may be necessary for him to catch a little different point of view and make some additional preparation for properly conducting such examinations. This is the crux of the problem for organized medicine. It will be successfuly solved but will take time. To activate 150,000 physicians and 118,000,000 people is a colossal task. Some results of periodic health examinations will be of interest. Among 17,000 adult white males recently examined, about 13 per cent were found to be overweight by more than 20 per cent above the usual standards for height and age. "Heavy dentistry" with suspected focal infection was found in 42 per cent of the cases; enlarged, septic or buried tonsils were discovered in more than a fourth of these adults; high blood pressure was found in about 7 per cent of the patients. Young persons, advised in hygiene, have a good opportunity for eradicating all adverse finding and by doing so add not only to their efficiency but to their longevity prospect. Thus, overweight was observed in only [illegible] per cent of the persons examined [illegible] the age of 25, [illegible] the age of 55 it was observed [illegible] almost 20 per [illegible] ns coming to the physician. [illegible] blood [illegible] rcentage of less than 5 in [illegible] of 10 in those between 45 and 54, and more than 20 in those beyond 55 years of age. The young people who were apprised of their condition by the physician have better longevity prospects now when they can safeguard themselves than they could have had if no examination or advice had been given them.

D'Arsonval Current in the Removal of Tonsils

Dr. Julian Buff, Atlanta: It occurred to me some months ago that by making a veder loop with a detachable metal tip, the shaft part of the instrument being insulated, the tonsil could be engaged more easily than with a tip made of hard rubber, or a metal tip covered with rubber. This instrument has proved very satisfactory. The method I use now has proved to be the most satisfactory way of removing tonsils, whether it is used with local or general anesthesia. The negative wire of a high frequency current machine is attached to the Beck instrument and then the tonsil is caught with a pair of insulated forceps except the tip, which serves as the positive pole, and then the current is turned on with a foot switch and the wire in the Beck instrument pulled taut until the tonsil is removed, which requires about three or four seconds, using 200 or 300 miliamperes of current. Operators who are beginners should not try this method; in fact, no one who is not adapted to the use of the Beck instrument and uses it with marked rapidity. This method has been used in thousands of cases and no explosion has been reported, and if one should happen it will be due to the carelessness of the operator. Advantages over the old method are: absence of blood, sealing of the lymphatics, less pain following the operation, less danger of secondary hemorrhage, faster healing, less scar tissue, less nausea when ether is used, and less fatigue to the operator.

Supracondyloid Fracture of the Elbow

Dr. Grady N. Coker, Canton: An accurately flexed, accurately reduced supracondyloid fracture will hold itself in place provided flexion is maintained. A simple sling is all that is needed. We have treated twenty-five cases by this method; twenty-one were dismissed cured and four with fair results. Our percentage of cures was 84. Early passive motion was a big factor in our results.

Subdiaphragmatic Abscess: Suggestions for Prevention

Dr. L. W. Grove, Atlanta: I feel that a great deal may be done toward the prevention of subdiaphragmatic abscess. This is accomplished by a more detailed supervision of the postoperative management, of acute suppurative conditions, of the right abdomen. The condition usually arises from some suppurative process in this location, and if certain principles of drainage were more strictly adhered to the condition would occur less frequently. The second precaution to be taken in suppurative conditions of the retrocecal space is supervision of postoperative posture. If these patients are allowed to remain prone in bed for a long time there is a tendency for the infection to gravitate upward toward the right kidney pouch, which favors a subsequent subdiaphragmatic infection. These patients should assume the Fowler position early. This not only encourages increased drainage but also causes relaxation of the abdominal muscles, which is an added comfort to the patient with this condition. The active treatment of subdiaphragmatic abscess is necessarily surgical, as soon as practical, after the diagnosis is made. The mortality rate is directly proportionate to the duration of the abscess. There is an increase of 15 per cent in cases in which operation is delayed longer than seven or eight weeks.

The Phosphatic Index

Dr. G. Y. Moore, Cuthbert: In the proper diagnosis of a case the medical profession is coming more and more to recognize the importance of the phosphatic index, which gives an estimate of the nerve energy as controlled by nutrition of the system. All the trillion cells, muscle, bone and fluid that make up the human body are fed by the flow of blood, constantly propelled by the nervous system. The medical profession cannot find a better field for its future researches than an exhaustive study of the position of the blood and nerve cells in the building and upkeep of the body in the life of man.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Incidence of Dysentery and Diarrhea Among Infants.—In a group of 628 white infants under 2 years of age, representative of the poorer middle class, from 7.5 to 13 per cent developed dysentery during the summer of 1925, and 27 per cent developed simple diarrhea. Among those not exclusively breast fed the incidence of dysentery was from 10 to 17 per cent and of diarrhea 33 per cent. Of all the cases of gastro-intestinal disturbance encountered by Wilkins, from 19 to 33 per cent were caused by dysentery. Dysentery is of much longer duration than "simple diarrhea," lasting more than two weeks in 65 per cent of the cases. When breast-fed infants are excluded, there is approximately the same frequency of gastro-intestinal disturbances during the first and second summer of life.

Experimental Serum Therapy of Dysentery.—A vaccine containing two billions each of five strains of Flexner dysentery bacilli was given by Wilkins by mouth on three successive days to 107 infants under 2 years of age. The frequency of dysentery among the infants who received the vaccine was identical with that among a control group of 369. The vaccine did not protect against dysentery.

Agglutination Reactions of Dysentery Bacillus.—Fulton and Berry assert that agglutinating properties can be produced in the serum of rabbits by the oral administration of killed dysentery bacilli.

Treatment of Enuresis.—In treating thirty-nine children having enuresis, Friedell found that the psychic treatment in the form of a hypodermic of sterile water proved successful in 87 per cent of the cases. In patients whose urine showed a persistent reversal of concentration, when the specific gravity of the day specimen was greater than that of the night, the treatment proved a failure. In borderline cases in which the specific gravity of the urine during the day was equal to or slightly greater than that of the night urine, a cure usually was obtained but with more difficulty than in patients with a normal concentration.

Dynamic Action of Food on Metabolism.—The effect of food on the metabolism of two normal infants, aged 3 and 4 months, was studied by Levine et al. in thirteen carefully controlled calorimetric observations of from two to six hours' duration. Fat, milk and protein meals raised the metabolism of one infant 8, 4 and 15 per cent above the basal level. The other infant reacted to the fat, milk, dextrose and protein meals by respective increases of 1, 9, 8 and 17 per cent above the basal level in the three hours after ingestion.

Dressing for Breasts of Nursing Mothers.—DeBuys applies five strips of adhesive plaster to the chest in such a way that the breasts are held perpendicular to the chest wall and pointing directly in front of the mother. They are supported in this position with a minimum of pressure being made against the chest wall; that is, the breast is not being pressed down. There is no compression of the mammary glands, no obstructions to any of the ducts and no twisting of the nipples; hence the milk may be secreted without restriction and may be allowed to flow freely without obstruction, and the natural leakage of the excess milk may take place in a normal way. One strap lying above the breast, one below, two straps crosswise and one between the breasts comprise the dressing.

Pyopneumothorax in Infants.—Johnson analyzed ten cases. All the ten patients probably had pleuropneumonia from the onset, and the pyopneumothorax was caused by a ruptured subpleural abscess. The similarity of the conditions found in three necropsies was striking. All three cases showed rupture of the lung in the upper lobe, a thick pleural exudate with interlobar adhesions, collapsed lung with one or more abscesses and bronchopneumonia. These are the youngest infants reported with pyopneumothorax complicating pneumonia, two being 1 month old.

Palmar and Plantar Keratodermia.—A case of keratodermia palmaris et plantaris of the congenital hereditary type is described by Olmsted. The previous occurrence of associated similar lesions in the circumoral and circumanal regions has not been reported.

Nonoperative Treatment of Intussusception.—Retan has been successful in using a method of injection of barium under the fluoroscope, with manual pressure for the relief of intussusception. He believes that in properly selected cases this method can be used with comparative safety.

Streptococcus Meningitis of Otitic Origin.—A case of bilateral otitis media and mastoiditis is reported by Huenekens and Stoesser with meningitis as a complication. This meningitis yielded a spinal fluid positive for pneumococcus by smear and for streptococcus by smear and culture. The streptococcus was of the hemolytic type. The path of infection from the middle ear and mastoid to the meninges was not determined.

Anthocyaninuria.—Attention is called by Poole to a condition which apparently occurs rarely, that is, pigmentation of the urine following the ingestion of red beets (beta vulgaris), and which might readily be mistaken for other conditions in which red pigment appears in the urine.

Blood Calcium Deficiency in Obstructive Jaundice.—In three cases of human jaundice, one of catarrhal jaundice, one of obstructive jaundice due to carcinoma of the head of the pancreas, and one of hemolytic icterus, seen by Buchbinder and Kern there were found low serum calcium values, which approached the normal with decrease of the jaundice. In puppies subjected to common duct ligation there occurred a progressive decrease in blood serum calcium, reaching approximately half the normal value.

Blood Regeneration in Severe Anemia.—Whipple and Robscheit-Robbins assert that beef marrow powder or cooked beef spleen are not especially potent food factors to promote hemoglobin regeneration in severe anemia. Bone marrow powder, from 30 to 40 Gm. daily, will cause an increase of from 20 to 25 Gm. of hemoglobin per two-week period over the control level. Brain tissue is a favorable diet factor for hemoglobin regeneration in severe anemia. A diet intake of from 200 to 300 Gm. cooked brains a day will cause an average increase in hemoglobin production of from 20 to 25 Gm. per two-week period above the control level. Pancreas is a favorable diet factor, and on an intake of from 200 to 300 Gm., there results an average increase in hemoglobin of 35 Gm. per two-week period over control periods. These reactions do not compare with the enormous increases in hemoglobin production during heavy feeding with liver or kidney.

Value of Fruit Diet in Blood Regeneration.—Experiments made by Robscheit-Robbins and Whipple have shown that apricots and peaches contain diet factors which are very favorable for hemoglobin regeneration during severe anemia. The addition of 200 Gm. of this cooked fruit to the daily standard diet may cause an average output of from 40 to 45 Gm. of hemoglobin per two-week period, over and above the standard control periods. For hemoglobin regeneration in simple anemia, these fruits are far superior to all dairy products. Dried fruits are as efficient as fresh fruits in the promotion of hemoglobin regeneration in anemia. Raisins and fresh grapes are somewhat less favorable than peaches and apricots for hemoglobin production in simple anemia. Apples, fresh and dried, show considerable variation but average about the same as grapes and raisins. Prunes come in the class with apricots and peaches. Raspberries (black, fresh) are practically inert as regards hemoglobin regeneration in anemia.

Effect of Insulin on Blood Calcium.—Brougher states that in both normal and parathyroidectomized dogs, the blood calcium is increased for a period of two and one-half hours following the administration of insulin.

Regulation of Respiration; Blood and Tissue Acidity.—Experiments made by Hertzman and Gesell support the view of the lack of correspondence between changes in acidity in the blood and in the tissues. The results agree with the theory that the acidity of the respiratory center is important in the control of pulmonary ventilation. They are not in disagreement with a direct effect of oxygen on pulmonary ventilation by changes in the state of oxidation of the respiratory center.

Bilirubinemia in Obstructive Jaundice.—Bollman, Sheard and Mann found that the ligation of the common bile duct after extirpation of the gallbladder is followed by an immediate rise in the bilirubin content of the blood, and it continues to increase at a uniform rate for several hours after this operation. Studies of the pressure in the common bile duct in these experiments showed that the maximal pressure was obtained almost immediately, and the progressive and uniform increase in the bilirubin content of the blood followed the application and maintenance of this pressure. If submaximal pressure is maintained in the common bile duct, bile continues to be excreted, but there is retention of bile pigment which produces hyperbilirubinemia. From these and other considerations, it would appear that the increasing intraductal pressure of obstructive jaundice early incapacitates the hepatic cells, so that bile pigment is not absorbed from the blood stream and the liver and biliary ducts do not become saturated with bilirubin.

Scarlet Fever Due to Infected Food.—Simultaneous occurrence of three geographically distinct outbreaks of sore throat and scarlet fever, apparently all due to a single contaminated food, are analyzed by Scamman et al. At least 138 of 592 persons attending the banquets at which the food was served developed illnesses. In ninety-eight cases the illness was undoubtedly scarlet fever. In forty the evidence is not sufficient to warrant a positive diagnosis. Evidence is presented to show that the source of infection was probably the lobster meat in a lobster salad. The approximate time of contamination of the lobster meat is evident, but the carrier or missed case responsible for the contamination could not be definitely identified. The occurrence of outbreaks of scarlet fever and sore throat from a common source of infection, with secondary cases of scarlet fever following contact with sore throat patients, show the importance of sore throats in the spread of scarlet fever. These might better be classed as cases of scarlet fever without eruption. Experiments were carried out which indicate that a hemolytic streptococcus may remain alive in lobster salad for a period long enough to infect those who partake of the salad.

Testing Germicidal Efficiency of Disinfectants.—A new method for testing the germicidal efficiency of disinfectants and antiseptics is proposed by Reddish. The test is based on the well known technic of the Rideal-Walker and Hygienic Laboratory methods. The best features of both these tests are retained and the most objectionable ones are eliminated. Instead of using only one test organism, as specified in the Rideal-Walker and Hygienic Laboratory methods, it is recommended that representatives of the most important groups of pathogens be used in a simplified method. Detailed procedures are given for *B. typhosus* and *Staphylococcus aureus*, and tentative methods are outlined for *B. diphtheriae*, *B. tuberculosis*, the pneumococcus bacillus and *Streptococcus hemolyticus*. A standard of resistance to phenol (carbolic acid) for each of these organisms, with the exception of *B. tuberculosis*, is given, and when they are used for testing the germicidal powers of disinfectants and antiseptics, they should show the resistance to phenol here indicated. It is not recommended that the manufacturers of disinfectants and antiseptics give the phenol coefficients of their products against all the pathogens used in this test, but they should be sure that the dilutions specified for their products will kill the pathogenic micro-organisms which it is desired should be killed.

Health Problems of Mexico.—Hoffman is of the opinion that health conditions in Mexico are making progress, and that the time is not far distant when the death rate will fall considerably below what it has been in years past. Malignant diseases are relatively much less common in Mexico than in the United States. Among the Pueblo Indian population, cancer also is extremely rare. Among the Mexican population, the prevailing type of cancer is of the uterus. Cancer of the breast is seldom found. Cancer of the stomach, intestine and rectum, as well as of the skin, is also comparatively rare.

Archives of Dermatology and Syphilology, Chicago

15: 527-646 (May) 1927

Analysis of One Thousand Cases of Congenital Syphilis. C. M. Smith, Boston.—p. 527.
*Bismuth Thioglycollate in Treatment of Syphilis. O. M. Gruhzit, E. Lyons and R. Perkins, Detroit.—p. 550.
*Acne Bacillus. L. W. Ketron, Baltimore.—p. 568.
Case of *Poikiloderma Atrophicans* Vasculare. K. M. Bowman and E. C. Clark, Boston.—p. 583.

Bismuth Thioglycollate in Syphilis.—Gruhzit et al. report that bismuth thioglycollate does not produce any injury; albuminuria is not produced; the blood urea nitrogen is not affected by it, and histologic studies indicated that a dose of 2.6 mg. per kilogram does not cause any changes in the liver, spleen and kidneys. Bismuth thioglycollate is absorbed from the site of injection in less than two hours. From about 20 to 40 per cent of bismuth appears in the urine and feces within seventy-two hours. The greatest part of it is eliminated through the kidneys. The spirocheticidal value increases with the quantity of the drug given. The minimum effective dose is about 1.3 mg., while the optimum spirocheticidal dose is from 2 to 2.5 mg. per kilogram. A limited clinical experience indicates that bismuth thioglycollate produces a somewhat more rapid improvement in lesions than do the insoluble bismuth compounds. It does not cause any lumps or pain at the site of injection when administered in water solution. The patient can be saturated readily without danger of cumulative action. The Wassermann reaction was influenced rapidly.

Acne Bacillus.—A bacillus on the skin, with cultural requirements and distribution similar to the acne bacillus, is described by Ketron. Because of this general similarity it is regarded as a variety of the acne bacillus and is designated acne bacillus B. The usual form is referred to as acne bacillus A. The B variety differs from the A variety principally in its more rapid growth, the absence of zoning in deep shake tubes and the occurrence of certain characteristic involution forms in anaerobic cultivation. Other differences in the appearance of the growth of the two varieties and in the fermentation reactions are described.

Archives of Neurology and Psychiatry, Chicago

17: 571-722 (May) 1927

Gastroduodenal Ulcers and Autonomic Imbalance. H. G. Wolff and E. W. Thomas, New York.—p. 571.
*Mechanism of Compression in Case of Tumor of Cerebellopontile Angle. W. F. Schaller, San Francisco—p. 609.
*Infantile Type of Family Amaurotic Idiocy. J. H. Leiner and S. P. Goodhart, New York.—p. 616.
*Postencephalitic Respiratory Syndromes. S. E. Jelliffe, New York.—p. 627.
*Rôle of Syphilid in Parkinsonian Syndrome. I. Pardee, New York.—p. 662.

Tumor of Cerebellopontile Angle.—The case reported by Schaller was of a typical tumor of the acusticus of slow growth which presented a marked cerebellar incoordination but lacked any indications of optic edema, symptoms of intracranial pressure and facial paralysis. The choroidal changes about the disks may well have resulted from a former papillitis, due to transient fluid block. The compression of the brain stem was not marked, as the tumor extended upward and outward at the expense of the cerebellar hemisphere and the middle cerebellar peduncle. The lack of degeneration in the dentate nucleus, superior peduncle and red nucleus suggested that the cause of the cerebellar incoordination should be sought elsewhere. The evident cause was found in the degeneration of the middle peduncle and of the restiform body, and in the degeneration of the descending vestibular root, both of the latter degenerations being dependent on the unilateral destruction of the vestibular nerve root.

Infantile Type of Family Amaurotic Idiocy.—The two cases reported by Leiner and Goodhart represent clinically the classic picture of Tay-Sachs' disease, but in some points differ anatomically from the classic types.

Postencephalitic Respiratory Syndromes.—Jelliffe reports two cases. One patient had a mild "cold in the head," and then a definite night delirium in which he saw "angels"; he was apparently quickly restored to health and returned to school. Then nasal sniffling and complaints of nasal obstructions began; there was then an automobile accident with nose implication, followed by respiratory sequelae. These were of the classic tachypneic variety, involving both intercostals and the diaphragm, with apneic phases, trance states, tetany cramps, occasional semiconscious lapses or trancelike states (which should be compared with the stuporous attitudes described by Bilancioni and Fumarola), sleep formula reversal, behavior anomalies, and then parkinsonism, with greasy face, sialorrhea, polyuria and polydipsia. The second patient had a mild cold in December, 1924, and then developed a talkative hypomanic state with hallucinations of bugs crawling on the ceiling, which lasted from two to three days. This was followed by a definite, fleeting diplopia and a deep lethargic state. Some weeks later a respiratory sequel and a pronounced sleep reversal formula began. The respiratory attacks were tachypneic, irregular and were participated in by both intercostal and diaphragm muscles. With increasing tachypnea and almost continuous (fishlike breathing) shar expirations, the parkinsonian attitude, sialorrhea, polyur and polydipsia appeared. The patient was still under tre.

ment three months later, in June, 1926, without appreciable improvement from conscious levels.

Rôle of Syphilid in Parkinsonism.—In Pardee's opinion, the parkinsonian syndrome of neurosyphilis is established as a disease entity, its recognition depending on the zeal exercised in the study of that syndrome.

Diagnosis of Chronic Maxillary Sinusitis.—Ninety-two per cent of the cases in the series reported on by Johnson could be diagnosed by means of the clinical data alone; in 67 per cent of the cases a diagnosis might have been made from the *roentgenographic observations*, while 98 per cent were diagnosed from the clinical and roentgenographic observations combined. Almost 19 per cent of the diseased maxillary sinuses could be traced to extension of dental infection. From the investigation of 300 maxillary sinuses, it would seem that a diagnostic puncture of this sinus is justifiable when there is any suspicion regarding its condition. This is the only means of making a correct diagnosis.

Torsion of Gallbladder.—Shipley reviews twenty-one cases of complete torsion of the gallbladder on record in the literature, and reports one new case.

Effect of Digitalis on Anesthetized Dog.—The observations made by Blalock offer a rational experimental basis for the belief that the *preoperative administration of digitalis may* be of considerable value in the preparation of certain types of patients for operation under general anesthesia. They also suggest that this drug should not be used during shock following operations.

Stomach Mucosa in Ulcer and Carcinoma.—Histologic examination made by Steinberg of twelve stomachs resected for ulcer of the duodenum or ulcer of the stomach and eight stomachs resected for cancer reveals that there are evidences of gastritis in the mucosa of all stomachs examined. Defects in the mucosa, erosions and small microscopic ulcers are frequently encountered. The changes are mostly limited to the distal part of the stomach in the area of the distribution of the pyloric glands. The evidences of gastritis are more pronounced in specimens resected for cancer.

Fractures of Skull.—Vance reviews 512 necropsies and sixty-one cases studied clinically.

Mercurochrome in Sinus Thrombosis and Lung Abscess.—*Mann reports two cases in which good results apparently* followed the intravenous injection of mercurochrome. One was a case of lateral sinus thrombosis coming on after a mastoidectomy done for a hemolytic streptococcus infection. The second case was one of lung abscess. A threepenny nail was removed from the right bronchus and immediately the boy, aged 6, began to cough up much offensive pus. Later, a large abscess of the lung developed. The boy's condition became progressively worse. Then the mercurochrome was injected, and recovery ensued immediately.

Place of Pediatrics in Undergraduate Teaching. A. G. Mitchell, Cincinnati —p. 241.

Historical Method of Teaching Clinical Medicine.—Emerson says that by greatly increasing its benefits to humanity, medicine makes it also necessary that medical schools graduate better and still better trained general practitioners Too *great loyalty to organization, too great a dependence on tools,* too great a pride in quantity production is one reason why the American medical schools today are not producing their best product. *Tools and organizations for standardized mass* production are splendid, but students should be taught, in the light of history, that they must live up, not to the most conspicuous elements, but to the best that there is in their culture, should understand its weakness, and should try to correct some of the evils which too great loyalty to that culture may produce. And finally, the lesson of history also suggests that American medical schools now should emphasize more not only greater accuracy in training but also the general culture of their graduates, their wider sympathies, in order to meet the wider social problems which medicine alone can answer.

Senior Students as Interns.—Oppenheimer feels that senior internships are of value to the student only when they are given in hospitals which are controlled directly as teaching units of the medical school or which have as staff members a sufficient number of the medical school faculty to insure to the student careful and persistent supervision of his work Internships in hospitals which are not intimately connected with the medical school are either positively detrimental to the student or of very questionable value. Senior internships tend to lessen the interest of the student in the scheduled work of the curriculum. They limit his opportunity for reading and study. Only students doing entirely satisfactory class work should be permitted to accept internships.

Experiment in Teaching Physiology.—The experiment described by Redfield consists in selecting a few of the more capable students who are expected to take the ordinary examinations in physiology, but who are excused from the regular laboratory work. Special laboratory experiments are substituted. These laboratory experiments reduced the amount of laboratory instruction one-half Then for the other half of the time they are given reading to do. This reading consists in selected chapters from the principal monographs which happen to be available At the end of each week a conference is held to talk over the work which the students have been doing Redfield is inclined to think that too much reliance is placed in the laboratory method in elementary teaching "Like all material machines the laboratory course tends to get us in its grip. We get it organized, we get the outline printed, we get all the necessary pieces of apparatus, we get the stockroom boys trained and then the thing will run itself I think that that kind of a machine gets a momentum which carries us along and keeps us very frequently from thinking seriously about just exactly what each of these experiments really means for the education of the individual"

Use of Pathologic Museum in Teaching.—Karsner is convinced that the pathologic museum so arranged as to be readily available for the use of the clinical teacher has its place in the scheme of medical education Ideally, the use of fresh preparations should furnish the anatomic basis for clinical and pathologic studies Admittedly, this is not practicable because of the fact that the type of fresh material available does not often coincide with the clinical cases to be illustrated The museum must be sufficiently extensive to provide representative lesions of most, if not all, the clinical conditions which must be illustrated If there is a coincidence of fresh material and living patient, the opportunity to correlate should be utilized Otherwise, the museum is to be called on The teacher, however, must not fail to realize that the museum preparation is little more than a three dimensional picture of the lesion under study and demonstrate it accordingly It is to be recommended that every medical school devote a goodly amount of attention to building up a freely accessible and reasonably extensive pathologic museum, but this should be done with a realization of the limitations of this type of material

Incidence of Heart Disease in Massachusetts.—In the fifteen year period from 1910 to 1925, the mortality from heart disease in Massachusetts has apparently increased from 0.119 to 0.208 per cent (of the total population). White says that heart disease is by far the commonest cause of death in this state at the present time (in 1925 the mortality from cancer was 0.125 per cent, from tuberculosis 0.083 per cent, and from pneumonia, 0.057 per cent). The total death rate in Massachusetts has dropped in fifty years (1875 to 1925) from 2.15 per cent to 1.23 per cent, and the infant mortality has dropped in twenty-five years (1900 to 1925) from 15.6 per cent to 7.3 per cent Analysis of the etiologic factors responsible for 3,000 persons seeking medical help for cardiac symptoms and signs in hospital (1,000), general (1,000) and consultation (1,000) practice during the last few years in New England has indicated that about 80 per cent had organic heart disease and 20 per cent had functional disturbances alone Of the organic cases, the following types were differentiated "rheumatic," 54.5 per cent, coronary disease (arteriosclerotic) without hypertension, 20.5 per cent; hypertension without coronary disease, 13.5 per cent, hypertension with coronary disease, 17.5 per cent, syphilis, 4 per cent, hyperthyroidism, 3 per cent, subacute bacterial endocarditis, 2 per cent, angina pectoris, 21 per cent in consultation and 9.5 per cent in hospital practice; coronary thrombosis, from 3 to 6 per cent, and congenital heart disease, 1.5 per cent About one half of the "purely functional" cases were classed as "effort syndrome" (10 per cent of the entire series) Of the 3,000 cases, 2.5 per cent were styled "unknown," there being no reasonable possibility of fitting them into any etiologic group

Therapeutic Use of Radium Salts.—John states that he has used radium chloride in a variety of ailments with gratifying results. Many of the cases had resisted other types of treatment but responded promptly to this therapy. He has not observed a single bad effect in any of them. The treatment is simple to administer and apparently harmless in proper dosage, and the results obtained have been permanent.

New Streptococcus in Rheumatic Fever.—A new species of a nonmethemoglobin-forming, insulin-fermenting, bile-insoluble and toxigenic, gram-positive streptococcus was regularly isolated by Birkhaug from the tonsillar crypts and abscesses, and irregularly from the blood cultures, heart vegetations, feces and urine of persons stigmatized by rheumatic fever and its syndromes. In a study of the production of soluble toxins by streptococci isolated from rheumatic fever patients, it was found that among eighty-nine strains of *Streptococcus hemolyticus*, toxin was not demonstrated; among 247 strains of *Streptococcus viridans*, 47 per cent were toxin producers, and among sixty-eight strains of the nonmethemoglobin-forming streptococcus, 72 per cent were found to produce a soluble toxic filtrate, slightly weaker in potency than that produced by *Streptococcus scarlatinae* and *Streptococcus erysipelatis*. Among persons with a definite history of rheumatic fever and its syndromes, when tested intradermally with 0.1 cc. of a 1:100 dilution of the soluble toxic filtrate produced by the nonmethemoglobin-forming streptococcus, 56 per cent of adults and 76 per cent of children gave positive skin reactions, and when tested with 1:10 dilution of the toxin, 67 per cent of adults and 85 per cent of children reacted positively with lesions measuring more than 1 cm. in diameter within twenty-four hours after the injection.

Classification of Colon Bacillus.—Examination by Monias of seventy-five strains of *B. coli* gave two subdivisions: (1) strains that produce indole and creatinine (*Bacterium indolicum*), and (2) strains without these qualities (*Bacterium anindolicum*). Further subdivisions in both of these groups may be made according to their ability to ferment carbohydrates: varieties *communior*, *commune*, *aerogenes* and *acidi-lactici* corresponding to Jackson's nomenclature. A second group, *B. anaerogenes*, is characterized by the same qualities as the group *B. coli*, but differs in its inability to produce gas from carbohydrates. There are four subdivisions in this group, according to ability to produce indole and creatinine and to coagulate milk, or partial or total inability to do so. This forms a transition group between *B. coli* and *B. enteritidis*. The third group, *B. enteritidis*, differs from *B. coli* by the lack of power to coagulate milk and to ferment lactose. In this group, as in the group *B. coli*, two subdivisions are found: one with indole and creatinine production, the other without. In each of these groups there are again four classes, A, B, C, D, according to the fermentation of saccharose, raffinose and dulcitol.

Sewage Filtrate as Source of Bacteriophage.—Sewage filtrate, as tested by Caldwell with sixty-seven strains of gram-negative organisms, yields a potent bacteriophage for practically all strains of *B. coli* isolated from urinary infections, and for most of the other common gram-negative bacilli encountered in human diseases. The use of sewage filtrate as a source of bacteriophage will materially increase the number of urinary infections that can be treated with the bacteriophage, and will avoid confusion in the identification of resistant strains of bacteria.

Persistence of Botulinum Toxin in Canned Foods.—Starin states that both the A and B types of *Clostridium botulinum* are capable of producing toxin in corn, peas and salmon, that will withstand exposure to drying, light—both diffuse and direct—and seasonal variations of temperature for a period of at least ninety days. Putrefaction of vegetables and meats which were originally highly toxic does not cause a disappearance of the toxin. Peas, corn and salmon, exposed in a moist condition and highly contaminated with putrefactive organisms, yielded botulinum toxin after an interval of 122 days.

Impermeability of Small Intestine to Botulinum Toxin.—The duodenum and ileum of the rabbit were found by Dack and Wood not to be permeable to botulinum toxin. Some toxin was demonstrated in the blood from the duodenum after sixty minues, but not more than was found in the heart blood at the end of the experiment.

Temporary Ureteral Drainage. J. A. H. Magoun, Toledo, Ohio.—p. 463.

Renal Tuberculosis.—Thomas and Kinsella assert that every patient infected with tubercle bacilli is a candidate for renal tuberculosis. The physician and the patient may not notice any symptom indicating this infection, but repeated urologic examinations, including complete urinalysis and animal inoculation, will reveal many unsuspected cases. Tissue destruction with renal tuberculosis or renal phthisis is a late lesion that is most frequently encountered by the surgeon. The diagnosis and early treatment of the renal tuberculosis may prevent the development of renal phthisis. Renal infection with tuberculosis is through the blood stream. Bilateral infection is the rule. Renal tuberculosis may end in clinical arrest or cure. Sanatorium treatment is necessary if renal tuberculosis is to be arrested or cured. This is suggested following the surgical removal of one kidney, as well as with bilateral infections.

Gonophage.—The gonococcus during its process of autolysis produces a substance that is lytic to other gonococci. Clinical experience with gonophage has convinced Pelouze and Schofield that the gonophage does have some favorable action against the disease in some persons, and that other ways of using it might give better results. The occurrence of systemic and local metastases, as well as the presence of gonococci in the urethral and prostatic secretions in some patients long after the administration of gonophage, would suggest that it does not greatly affect the body immunity processes.

Stab Wound of Kidney.—Jeck's patient developed a perinephritic abscess, and following this a suppurative posterior mediastinitis. Death was caused by a suppurative peritonitis, the result of an acute suppurative nephritis.

Origin of Acetaldehyde in Bacterial and Animal Metabolism M D Whetham —p 35
*Achromobacter Perolens (n sp) Cause of "Mustiness" in Eggs A W Turner —p 57

Structure of Neuron Junctions of Spinal Cord—Tiegs states that collaterals are recognizable within the gray matter of the spinal cord by the fact that they undergo branching the point of branching being marked by a small triangular piece of protoplasm Most of the collaterals thus identified when followed along their length, emerge from the plane of the section, or become confused with other fibers But occasionally it is possible to trace these fibrils right into the *dendrites* *This is taken as direct evidence in support of the* view previously put forward on indirect evidence, that there is a direct neurone continuity in the spinal cord, the collaterals entering the nerve cells via the cell dendrites No evidence for the existence of synapses branching on the outside of the nerve cells has yet been found In support of the view that the neurofibrils are genuine cell structures, it is pointed out that under certain circumstances they may be seen in the unfixed nerve cell

Cause of Mustiness in Eggs.—Turner is convinced that mustiness in eggs is caused by the infection of the eggs with a specific organism, *Achromobacter perolens* (n sp) The possibility of eggs becoming infected in the body of the fowl is remote, since the organism will not grow at the temperature of the fowl's body Since the organism grows at room temperature, it is probable that infection takes place after the egg is laid As the organism will grow slowly at or slightly above 0 C, it is possible that it may infect eggs in the cool stores

*Bacillary Dysentery in Aberdeen R Richards —p 31

Tachycardia and Petit Mal.—Sutherland states that in connection with attacks suggestive of petit mal there may be present at these times a condition of tachycardia, with pulse rate over 160 a minute, without other obvious cardiac changes An attack is often definitely induced by excitement (nervous shock) or exertion (i e, running) While an organic basis of disease in the heart may be present, a similar condition of paroxysmal tachycardia with symptoms may occur in hearts organically sound

Bacillary Dysentery in Aberdeen—Richards emphasizes the fact that the occurrence of true dysentery bacilli among the general population is not so rare as is usually stated The treatment by magnesium sulphate is almost specific for bacillary dysentery, but it must be ruthless from 15 to 30 grains, in water, at least six times during the first day, with a daily diminishing number of doses as the symptoms begin to clear, and with a single morning dose for several days after these have all cleared With this, diet is almost as important

*Transplantable Fibrosarcoma of Fowl A M Begg —p 147

Relation Between Amino-Acids and Wassermann Reaction—In experiments in vitro and on rabbits, and in parallel determinations of blood amino-acid nitrogen and the Wassermann reaction in a number of hospital patients, both syphilitic and nonsyphilitic, Fowweather and Gordon failed to demonstrate any relation between the amino-acid content of blood and its Wassermann reaction

Bactericidal Action of Mercurochrome—The conflicting reports made with regard to the alleged bactericidal efficiency in vivo of mercurochrome led Colebrook and Hare to make in vitro as well as in vivo experiments Serum derived from human blood treated with mercurochrome (from 1 40,000 to 1 10 000) did not have bactericidal power for staphylococcus or hemolytic streptococcus Human blood (defibrinated) which had received an addition of 1 10 000 of mercurochrome had considerably less power to kill staphylococci than the same blood without mercurochrome Bile derived from a rabbit which had been given a maximal dose (5 mg per kilogram) of mercurochrome did not possess bactericidal power for *Bacillus typhosus* The normal bactericidal power for *B typhosus* possessed by the serum of this rabbit was not increased by the injection of the drug These results suggest that no direct bactericidal effect, either in the blood stream or the bile is likely to follow the administration of mercurochrome They therefore do not afford support to the recommendation that the drug should be employed in septicemia and for the treatment of typhoid carriers

Influence of Blood Coagulation on Bactericidal Power.—Walsh and Harmsworth assert that blood develops bactericidal properties during the preliminary stages of clotting that bring about the formation of thrombin

Immunity in Experimental Herpes—It is shown by Bedson and Crawford that recovery from infection with the virus of herpes in the guinea pig is accompanied by the development of a general immunity to this virus, and that the serum of these convalescent guinea pigs possesses the power of *neutralizing the herpes virus in vitro* Further it has been found possible to increase this viricidal activity of the serum by hyperimmunization, and with the hyperimmune serum so obtained to produce a definite degree of passive immunity They have not been able to demonstrate that tissue emulsions from herpes immune guinea pigs possessed any neutralizing power for the herpes virus in vitro

Transplantable Fibrosarcoma—A slow growing fibrosarcoma of the fowl has been propagated by Begg, with living cells for four generations

Surgical Treatment of Vocal Cord Paralysis—Colledge and Ballance state that the best method of anastomosis of the recurrent laryngeal nerve to the phrenic nerve, so as to obtain recovery of movement of the paralyzed vocal cord in rhythm with the movement of the normal cord, remains to be determined

Traumatic Auricular Fibrillation—Five cases are recorded by Hay and Jones in which fibrillation resulted from trauma in one case the exciting factor was a powerful electric shock in the remaining four the exciting factor was sudden physical exertion putting an unexpected and undue strain on the heart In four of these men there was no evidence that the heart was diseased or abnormal and up to the onset of fibrillation they were living active normal lives The authors hold that the evidence justifies the view that sudden strain may, and frequently does, initiate auricular fibrillation and induce cardiac failure in men and women with diseased hearts, in fact, that fibrillation may result from physical strain in hearts that are apparently normal so far as can be determined by ordinary clinical methods

Treatment of Epidemic Encephalitis.—It is suggested by Eden and Yates that the infection in epidemic encephalitis is a symbiotic process In the first place the nasal mucous membrane is injured by one of the catarrhal group of organisms, and subsequently the virus of encephalitis is inhaled, passes through the injured mucous membrane, and thus enters the tissues, reaching the brain possibly by the perineural lymphatics In support of this there is a fair amount of evidence that for the transmission of the disease from one individual to another the virus of epidemic encephalitis must fall on mucous membrane previously altered by inflammation of such a character that its power of absorption of fluids in contact with it is greatly increased The initial injury to the nasal mucous membrane is generally remediable by treatment, and if remedied, it would appear that the virus of encephalitis cannot pass into the tissues, and patients become more susceptible to treatment by drugs Nasal treatment aims, not at curing epidemic encephalitis, but at preventing the admission of fresh virus into the tissues In those cases in which actual destruction has occurred in the central nervous system (a system in which regeneration is impossible), the most that can be said for washing out the nasal sinuses is that further irreparable injury is hindered, and in many cases appears to be prevented The parkinsonian gait and posture is rarely completely removed without the use of remedial exercises

Experimental Production of Stone in Bladder.—Stone in the bladder has been produced by McCarrison in rats by means of an ill balanced diet composed of foods commonly used by man The stones were of the phosphatic variety The main faults of this diet were (*a*) absence of protein of animal origin, (*b*) deficiency of vitamin A, and (*c*) excess of earthy phosphates To these faults there may possibly have been added a toxic action of the diet itself on the urinary tract

Pernicious Anemia in Elderly People.—Templeton reports two fatal cases occurring in women over 70 years of age. One woman was 75 at the time of death

Preparation of Antirabies Vaccine—The virus used by Nicholls and Burgess has been adopted in the Indian institutes This consists in preparing the emulsion of the brain and spinal cord with a solution of phenol (carbolic acid) of a strength which will kill the virus in twenty-four hours at 7 C, but which will not destroy its immunizing properties

Copper Aceto-Arsenite as Anopheline Larvicide.—There are many factories in Ceylon in which various articles are manufactured from coconut fiber, and this results in the accumulation of large mounds of coir dust which is of no commercial value The bulk of this can be sifted rapidly through a wire gauze sieve of thirty strands to the inch, and a very fine dust is obtained A number of experiments were carried out by Nicholls to compare this diluent of paris green with road dust It was found that a mixture containing not more than 2 per cent by weight of the paris green is both effective as a larvicide and safe so far as poisoning is concerned

Transmission of Trypanosomiasis in Rabbits.—A hutch rabbit was found infected with *Trypanosoma nabiasi* Channon and Wright studied the mode of transmission Intravenous inoculations of infected blood into normal rabbits are not always followed by an infection Infestation of rabbits with infected fleas was found to be a reliable method of transmitting the disease Trypanosomes develop in the posterior station of the flea The bite of fleas containing the developing trypanosomes is not infective but, if their alimentary canals are eaten by rabbits, infection of the blood stream follows An attack of trypanosomiasis confers an active immunity which lasts at least six months It was not found possible to infect rats, mice or guinea-pigs

Preparation of Staphylococcal Hemolysin—The method of preparing staphylococcal hemolysin described by Bigger et al consists in suspending staphylococci from a solid medium in saline solution, and in freeing the fluid from cocci by centrifugalizing The lysin so prepared is said to be purer than any previously described, since it is free from the various adventitious substances present in broth cultures

Hemolytic Streptococci in Tuberculous Sputum—Of 119 patients suffering from pulmonary tuberculosis, twenty-two were found by Cumming to have hemolytic streptococci, indistinguishable from the ordinary hemolytic streptococci of surgical practice, in the sputum Of the 119 patients, eighty-nine have been shown to have in the sputum a streptococcus which has been termed *S pseudohemolyticus* This streptococcus bears marked resemblance to *S hemolyticus,* but is easily distinguished from it and from *S viridans* by cultural and serologic methods

Benign Polyp of Esophagus—The tumor described by Dyke was discovered at postmortem examination The patient had complained of inability to swallow either solid or liquid A diagnosis was made of a stricture, probably carcinomatous, at the level of the sixth dorsal vertebra with a dilatation just above it A gastrostomy was performed The patient's condition, which had been very bad at the time of the operation, became rapidly worse, and death occurred on the fourth postoperative day At *postmortem examination* it was at once apparent that there was no stricture of the esophagus, which was, in fact, enormously dilated The dilatation commenced at the level of the upper border of the cricoid cartilage and increased gradually and evenly to the level of the diaphragm, where the diameter was about 8 cm Palpation revealed a soft mass in the lumen of the viscus, which was found to be a pedunculated polyp attached to the anterior wall of the esophagus at the level of the cricoid cartilage and extending to the cardiac orifice, through which it protruded The length of the tumor from the attachment of the pedicle to the tip was about 20 cm It consisted of areolar tissue similar to that normally found beneath the esophageal epithelium, with a covering of squamous epithelium identical with that lining the esophageal tube

Effect of Ultraviolet Rays on Sarcoma—Illingworth and Alexander endeavored to demonstrate in filtrates rendered [illegible] by irradiation the presence of one or the other of Gye's factors, the "virus' and the "specific factor" The methods employed for inactivation of the fluids by heat, by prolonged incubation and by chloroform have been in every respect similar to those described by Gye From the experiments described, it would appear that neither of the two factors can survive exposure to ultraviolet irradiation

Streptococcal Content of Throat—Fox and Stone assert that the streptococcal content of the human throat maintains a constant standard as regards both quantity and type, the only important change associated with local pathologic conditions is an invasion by hemolytic streptococci

Epithelial Heterotopias of Alimentary Tract.—Taylor cites cases illustrating (1) the congenital heterotopias, superficial, of gastric intestinal and duodenal type, of submucous glands, intramural cysts adenomyomas and accessory pancreas, and (2) the acquired heterotopias of the hyperplastic and regenerative types

Paget's Disease of Nipple—Muir suggests that both Paget's disease and ordinary carcinoma are possible sequels of the same disease—intraduct carcinoma

- Anaerobic Cultivation in Single Small Tubes F P G de Smidt—p 354

Heredity, Growth and Nutrition—Henderson endeavors to show that in growth heredity plays a part as well as nutrition Further, as regards nutrition, an adequate diet with the proper constituents in the proper proportions is of the utmost importance There are however, several environmental factors, such as psychic influence, exercise and sunlight, which play their parts

Moderate Quinine Dosage in Malaria—Hodson pleads for a moderate dosage of quinine in the treatment of malaria 10 grains (065 Gm) after breakfast and 10 grains after dinner is said to be sufficient This dose is based on the rate of excretion, which is about 10 grains to the pint of urine This dosage is given to a patient with an acute attack and is continued for four days at the end of which time the patient is afebrile, no organisms are to be found in the peripheral blood, and to all appearances the cause of the illness has been absolutely controlled At this stage, the administration of quinine is stopped for two reasons (1) because the result of its administration has been so satisfactory, and (2) because any further immediate dosage gives rise to quininism in one of its many forms By stopping the administration of quinine as soon as its effect has been established, time is allowed for the excretion of all the drug before its use is recommenced, there can be no possibility of organisms becoming quinine resistant and, more than that, a period is allowed during which the resistance of the individual is stimulated Three days' freedom from quinine is the first allowance, which is then followed by a further three days of quinine administration, followed in turn by four days off This system of giving and withholding quinine is carried on for from two and a half to three months and is varied according to its effects which are judged at weekly or, later on, at fortnightly examinations of the patient

Muscular Mechanism of Respiration.—Certain states of mind, certain somatic and visceral stimuli, senescence and respiratory stress produce changes in the mode of breathing These changes entail undue activity on the part of certain muscles, which activity Briscoe believes to be generally of the nature of enhanced and persistent tonus. This occurs at the expense of the resting period of these muscles. If transient, it may not be of moment, but if persistent it will soon produce exhaustion. Activity in muscles calls for a vast increase in blood flow, and in the case of repeated movement (phasic) contractions, this is provided by direct massage to the capillaries and veins. Persistent tonic contraction, so far from helping the circulation, actually impedes, so that exhaustion ensues leading to distress. Distress is appreciated by the patient as pain, and calls for investigation and treatment.

Light Treatment of Surgical Tuberculosis.—It is urged by Gauvain that the value of general light treatment in any particular district depends only partially on the intensity and nature of the sunlight available. For some persons very intense light is the reverse of beneficial, particularly in feeble cachectic patients with little power of response. What is of greater importance is the application of varying light and other stimuli, graded and varied according to individual needs. Patients able to respond well will do well under intense stimulation, whereas for weaker, cachectic and elderly patients, great caution should be exercised and only slight stimulation is at first appropriate. The search now being made for a suitable therapeutic artificial light of constant character and intensity, readily measurable by physical means or by individual biologic responses, and constant in application, is in Gauvain's opinion illogical, and clinical evidence supports this view. Rather, he says, should the method of varying stimuli be adopted, graded to produce optimum responses in individuals who are themselves susceptible to infinite changes in reacting power. Light is a tonic both to the mind and to the body, and its effect in stimulating mental activity is one of the most interesting and not the least valuable phenomenon associated with the complex and fascinating sequelae following light treatment in surgical tuberculosis.

Low Renal Threshold in Diabetes Mellitus.—In the majority of cases of diabetes mellitus, the renal threshold for sugar becomes raised; Shapland's case is unusual in that a true defect in carbohydrate storage has been associated with a very low renal threshold. In addition, the case was complicated by a diseased gallbladder and a marked degree of overweight. The method adopted to combat acidosis by giving a diet liberal in carbohydrates but restricted in fats before the operation, with plenty of fluid, sugar and insulin, with blood sugar control for several days after operation, led to a successful issue. Eight months later, this patient was free from all symptoms of the disease; his fatigue had gone; the urine had remained sugar free, and he felt strong and well. It seems probable that the removal of the diseased gallbladder was the deciding factor in alleviating the diabetic condition.

Iodism and Edema Glottidis.—Snell and Savin relate the case of a woman who developed iodism following the administration of 15 grains (1 Gm.) of potassium iodide at night and a total of 25 grains (1.62 Gm.) the next morning. She became very dyspneic, with some obstruction to respiration. Laryngoscopy showed edema glottidis. Breathing temporarily improved; but that evening a rapid tracheotomy had to be performed, with the patient dying and unconscious. The patient recovered.

Retained Testis in Childhood.—Fifty cases of inguinal retention of the testis have been treated by Southam and Cooper by placing the testis in the scrotum. In thirty-six cases good anatomic results were obtained; in fourteen the treatment failed. Two cases occurred in twins; in both brothers a retained testis, accompanied by a hernial sac, was found on the right side. There was no mortality in the series.

Iodine in Treatment of Exophthalmic Goiter.—Cole endorses the administration of compound solution of iodine in the treatment of true exophthalmic goiter. From 5 to 10 minims (0.3 to 0.6 cc.) of compound solution of iodine, three times a day, is a safe and efficient dose in most cases for the first few weeks' treatment, and 5 minims may be continued safely and with benefit to some patients for six months. An increase of symptoms during treatment, however, is an indication for a smaller dose. An abnormally firm thyroid, exceptionally severe nervous symptoms, or loss of weight during the first few weeks of treatment are warnings that compound solution of iodine may be dangerous.

Radiotherapy of Tumors.—Observations made by Russ and Scott on more than 100 rats suggest that irradiation of the skin distinctly hinders the growth of the tumor.

Dietetic Treatment of Diabetes Mellitus.—Winn states that rest to the islands of Langerhans continues to be the essential principle in the treatment of diabetes mellitus, and this can best be secured by a moderate reduction in the diet without rest in bed and without insulin in the majority of cases. The Allen method he believes to be ineffective in emaciated patients, unnecessary in others and because of starvation (and consequent lowered resistance to infection), obnoxious and harmful in all. In the method described by Winn, the patient is examined once a week, and increases of 200 calories are made in the diet if the urine is "sugar free." By varying combinations of three "diet groups" (of 500, 600 and 900 calories), it is possible to supply completed diets ranging from 1,000 calories to any limit, with rises of from 100 up to 2,000. Just as it is the custom in lists of vegetables and fruits to strike averages for the carbohydrate content, so for meat and fish average figures have been used. Only a few exceptions and alternatives have been listed.

Systemic Blastomycosis.—The case reported by Cleland is said to be the first case since 1916. Several Australian cases of blastomycosis have been recorded. A "tumor" in the right iliac region was thought to be an inoperable sarcoma, but proved on microscopic examination to contain numbers of a yeastlike organism which was not identified.

*Biomicroscopy of Surface Capillaries. G. E. Brown and G. M. Roth.—p. 499.
Gravimetric (King) Determination of Basal Metabolism. H. S. H. Wardlaw.—p. 506.

Temperature and Pulse Rate in Disease.—Attention is drawn by Jones to the prognostic significance of the relations of temperature and pulse rate in cases of fever, and to the importance of certain independent variations of the pulse rate in other conditions. The fever of acute infections produces *a rise in pulse rate which closely corresponds with the rise* in temperature; conversely, when in any case under observation rises of these characters occur, an infection is to be inferred. In cases of good resistance, in which recovery occurs without injury to the heart muscle, the pulse rate falls with the temperature. Any delay in the fall of the pulse rate relative to the temperature is in proportion to the myocardial injury done. In fatal cases, there is a steady rise in pulse rate, irrespective of the temperature. In chronic disease, febrile or afebrile, a steadily rising pulse rate indicates progressive failure. Recovery is possible in acute cases, even with grave and prolonged disturbance of the pulse temperature ratio. Study of the graphic records of temperature and pulse on parallel charts is of great assistance in prognosis, both in acute and in chronic disease.

Biomicroscopy of Skin Capillaries.—Quantitative studies on the skin capillaries in the nail-fold and in other areas of the skin have been made by Brown and Roth in a large series of *normal and pathologic subjects.* The capillaries in the normal subject increase in length and become narrower with advancing age. The capillary flow becomes slower in the later periods of life, and there is an increased incidence of abnormal types after the fifth decade of life. In many cases of chronic glomerular nephritis, and in certain cases of severe primary hypertension, there are definite disturbances of the flow of the capillary blood and considerable contraction of the loops. In cases of Raynaud's disease and related vasomotor disturbances, there is diminished capillary tone and evident disturbance of the capillary flow in the different color phases characteristic of the former. In cases of polycythemia vera, the surface capillaries show distention of one or both segments and many new capillaries are opened up, thus permitting a larger exposure of capillary blood than obtains in the normal skin and forms the major basis in the production of the erythrosis.

Immunity in Frambesia.—A comparative study of the experiments with frambesia and with experimental syphilis, Ikegami says, shows that there is a difference in the mode of immunity in the two diseases. The reinfection comes out positive in syphilis only in the earliest stage of the infection, and becomes negative 100 days after infection. In frambesia, however, the reinfection comes out positive even 617 days after infection. The features presented in the two lesions in the reinfection are also different. In syphilis, the lesion due to reinfection is not in any way different from that of the first infection, although at times prolongation of the incubation period is encountered. In frambesia, the reinfection chancre is evidently milder, the incubation period being rather longer. The so-called true immunity is obtainable in the case of syphilis within from two to three months, while in frambesia the time required to produce true immunity is greatly prolonged; i. e., at least not less than twenty months.

J. Oriental Medicine, Dairen, S. Manchuria

6: 17-29 (March) 1927

*Scarlet Fever. T. Satake.—p. 17.

*Blood Diazo Reaction in Pulmonary Tuberculosis and Typhoid. T. Yamaguchi.—p. 27.
Venous Sinuses of Skull of Japanese. Y. Liu.—p. 29.

Streptococci in Scarlet Fever.—Hemolytic strèptococci were demonstrated by Satake in 92 per cent of 167 early cases of scarlet fever from the mucous membrane of the pharynx; in 24 per cent of sixty-seven convalescent cases, and in thirteen cases out of the 168 normal persons in whom nothing remarkable had been seen in the pharyngeal mucous membrane. In 95.5 per cent out of the forty-four cases of scarlet fever either in the foci or in the postmortem material, hemolytic streptococci were demonstrated. Streptococci were seldom demonstrated in the circulating blood, but the results of the blood examination immediately before death showed that three out of sixteen cases gave positive results on bacteriologic examination. Satake is of the opinion that the views of the Dicks on the etiology of this disease are debatable. The etiology or the pathogenicity of scarlet fever is still to be established. Satake also recognizes a condition of "parascarlet fever."

Diazo Reaction in Tuberculosis and Typhoid.—Yamaguchi applied the diazo test in fifty-five cases of tuberculosis, and in twenty cases of typhoid. Of the former, twenty cases of a mild nature were negative. When the symptoms became more pronounced, almost all the cases became positive, and the urine diazo reaction, which previously had been negative, also became positive. When the symptoms were severe, or before death, the reaction was negative. In the course of typhoid, and during the first week, the diazo reaction in the blood was wholly negative.

Determination of Fibrin in Blood in Various Dermatologic and Urologic Affections. A. Fujiwara.—p. 399.
Pharmacologic Study of Several Sympathomimetric Amines. M. Fujita.—p. 427.

Insulin-Like Substance Obtained from Appendix.—An insulin-like substance was extracted by Misaki from the mucous membrane of the appendix. It was not found in the mucous membrane of the stomach or small intestine. This substance definitely lowered the blood sugar content of a normal rabbit made hyperglycemic experimentally. The author believes that this substance comes from the pancreas, and aids in the formation of glycogen and in the regulation of the sugar metabolism.

Cartilage and Bone Deposits in Tonsil.—Tanaka and Oda regard the blood calcium as being an important factor in *these cases, three of which are reported by them.*

*Tuberculosis and Poisoning with War Gas E Sergent —p 545
*Effect of the Purification of Insulin in Favoring Phenomena of Hypoglycemia H Chabanier et al —p 577

Tuberculosis and Poisoning with War Gases—Sergent rarely observed tuberculosis among the immediate complications of poisoning with war gases On the other hand, he noted that the tardy occurrence of tuberculosis in war veterans is more and more frequent every year The author ascribes the fact to chance factors which favor the awakening of the disease and does not connect it with gas poisoning Of forty-eight veterans of the world war recently reexamined, twenty-two have a history of grave gas poisoning They present chronic lesions of the respiratory organs, so far, none suffers from tuberculosis Twenty-six have tuberculosis, which developed from three to eight years after the occurrence of an insignificant gas poisoning The respiratory lesions of the first group appeared under the form of chronic bronchitis, bronchopulmonary sclerosis, emphysema, bronchiectasis or asthma like dyspnea So long as tubercle bacilli are not found in the sputum or inoculation of guinea-pigs with the sputum is negative, the lesions are not considered as tuberculous

Rôle of Purification of Insulin Preparations in Phenomena of Hypoglycemia—Chabanier, Lebert Lobo-Onell and Lumiere assert that the morbid phenomena of hypoglycemia observed sometimes in the course of insulin treatment occur only with highly purified insulin About 600 000 injections of a slightly purified insulin were used by the authors in diabetic patients cured of glycosuria, and in nondiabetic patients with atonic ulcers Phenomena of hypoglycemia developed in a minimal number of cases, from occasional causes The relatively high percentage of hypoglycemia reactions in the American statistics is attributed to the use of highly purified insulin Foreign substances contained in the nonpurified insulin seem to reduce its hypoglycemia-inducing effect

Bulletins de la Société Médicale des Hôpitaux, Paris

51 491 565 (May 5) 1927 Partial Index

*Surgical Mask in Prevention of Contagion Armand Delille —p 523
*Note on Treatment of Anaphylactic Diseases with Peptone Chiray —p 525
*Peptone in Treatment of Anaphylactic Diseases Pasteur Vallery Radot and P Blamoutier —p 527
*Etiology of Arteritis Obliterans with Intermittent Claudication C Lian et al —p 534
Phrenicotomy for Tuberculous Lesions in the Pulmonary Apex R Burnand et al —p 542

A Simple Preventive Measure Against Tuberculosis and Infectious Diseases in Children—Armand-Delille suggests that tuberculous patients should wear a cloth mask (surgical mask) over the mouth when they are being auscultated He believes that this measure may save many members of the medical profession from tuberculous reinfection The method has been tried in children with measles The mask was applied when the children were moved from the measles ward to other parts of the building for roentgenologic or laryngologic examination or for ultraviolet-ray treatment Armand-Delille is persuaded that the measure arrested the spread of the disease

Note on Injections of Peptone in Treatment of Anaphylactic Phenomena—Intradermal injections of peptone by the Pasteur Vallery Radot and Blamoutier method were employed by Chiray in three cases of hay fever and in two cases of essential asthma The results, he asserts are encouraging He emphasizes that one series of injections is usually insufficient, and that successive series may not exert any effect

Intradermal Injections of Peptone in Treatment of Anaphylactic Diseases—Pasteur Vallery-Radot and Blamoutier recommend the use of intradermal injections of peptone in treatment of anaphylactic phenomena of the respiratory type Three years' experience has taught that the treatment succeeds chiefly in cases of hay fever and of essential asthma In the former it induces notable improvement, sometimes even cure The injections should not be begun before the coryza sets in, their preventive action being nil The peptone treatment is beneficial in cases of essential asthma in which the attacks are frequent The injections should be administered during the attack Patients thus treated were able to resume their usual occupations Patients with spasmodic coryza improved, but the relief was of short duration Fifty grams of peptone are mixed with an amount of water sufficient to make up 100 cc The first injection consists of 0 1 cc of the solution, the second, of 0 2 cc, the following, of 0 3 cc The last dose is never exceeded The injections are given every day, a series consists of twenty injections The solution must be injected into the skin, introduced beneath the skin, it may cause a phlyctena and consequent slough The normal local reaction is represented by a papule surrounded by an erythematous zone It disappears in about a week

Etiology of Arteritis Obliterans with Intermittent Claudication—Lian, Puech and Viau's study of the etiology of this disease is based on fifty-two personal cases In rare cases the cause is an acute or a chronic infection or an autointoxication, such as diabetes or gout Nutritional disturbances, occurring about the age of 50, are an important factor The role of syphilis is insignificant, while that of tobacco is considerable So-called Buerger's disease, the authors say, cannot be considered as a pathologic entity It is a clinical form of arteritis obliterans, occurring most frequently in Jews of Central Europe

*Mercury in Treatment of Myopic Choroiditis De Saint Martin —p 268
The Marcus Gunn Phenomenon M Joltrois —p 272
*Blindness in the New Born P Bregeat —p 274

Modifications of Mariotte's Spot in Various Eye Diseases.—Terrien emphasizes the changes in the blind spot observed in myopia choked disk and glaucoma In severe myopia, the spot is greatly enlarged it is surrounded by a zone of partial blindness The larger this zone is the less favorable is the prognosis of the myopia Enlargement of both Mariotte spots confirms diagnosis of cerebral tumor In glaucoma, an arcuate scotoma develops between the blind spot and the fixation point This scotoma appears early when the visual acuity and the peripheral visual field are still normal Scotoma of glaucomatous origin is reduced by the action of pilocarpine, other scotomas are not influenced by the drug In optic neuritis reduction of central vision and of central scotoma is associated with enlargement of the blind spot In this case miotics are without effect on the changes in Mariotte s spot

Value of Mercury Treatment in Myopic Choroiditis—De Saint-Martin uses mercury cyanate in treatment of macular choroiditis complicating severe myopia In three of four cases described, the central scotoma and the macular focus disappeared A notable improvement was manifest in the fourth case Intravenous injections are preferred to injections A series of twenty injections must sometimes be repeated

Partial Blindness of Congenital Origin—Bretagne calls attention to a form of congenital blindness in the newborn, not accompanied by any apparent changes in the eye The light reflex and the dilatation of the pupils are almost normal The base of the eye is unchanged At the age of seven months, the infants acquire partial sight The visual defect is associated with signs of physical and mental debility These cases should not be confounded with those of blindness from congenital cataract, or with those of temporary blindness from meningeal disease So far, the histologic lesions are uncertain They are evidently located in the optic tract or in the cortical centers

*Vasoconstrictor and Vasodilator Substances in Therapeutics C Abadie—p 579

Therapeutic Value of Vasoconstrictor and Vasodilator Substances—Abadie lists some of the diseases which result from vascular disturbances, justifying vasoconstrictor or vasodilator treatment In glaucoma, instillations of atropine reduce the vasodilatation in the eye vessels, this brings about improvement In case of optic atrophy, atropine is without effect Spasms of the central artery of the retina may cause blindness in one or both eyes Injection of 0 001 Gm of atropine into the orbit or beneath the conjunctiva improves spasmodic optic atrophy, it does not influence optic atrophy of organic origin Among auditory diseases, Meniere's vertigo appears to be due to an intensive vasodilatation of the auricular arteries The favorable action of vasoconstrictor substances confirms the theory In herpes of the ophthalmic nerve, the vesicles, phlyctenas and pustules developing on the forehead are explained by vasodilatation of the supra orbital arterioles, provoked by the herpetic virus Generalized pemphigus results from vasodilatation of arterioles in the skin A case of grave generalized pemphigus was cured with vasoconstrictor treatment Epinephrine combined with ergotin and calcium chloride is recommended in cases in which vasodilatation is responsible for the lesions

*Sensation of Electric Discharge in Multiple Sclerosis J Lhermitte et al—p 610
*Contraindication to Curettage in Uterine Fibroma R Leibovici—p 615

Sensation of Electric Discharge as an Early Sign in Multiple Sclerosis—Lhermitte, Levy and Nicolas call attention to an early sign of multiple sclerosis consisting in a recurring sensation of an electric discharge, similar to that from the faradic current It is perceived in the vertebral column and in the extremities The phenomenon occurs exclusively on active or passive bending of the head or of the trunk, never during sleep or rest A similar sensation is felt by patients with lesions following concussion of the spine In both conditions the sensation is due to mechanical irritation of axis-cylinders deprived of their myelin During bending, elongation of the spinal cord and its compression against the vertebrae causes the irritation

Contraindication of Curettage in Case of Uterine Fibroma.—Leibovici emphasizes the fact that fibroma favors the occurrence of abortion In case of hemorrhage or retention of the placenta, curettage should never be used, especially if the fibroma is situated beneath the uterine mucosa Denudation of the fibroma may aggravate the hemorrhage or cause infection of the tumor Vaginal fibromectomy performed in the course of an infection is extremely dangerous Total hysterectomy by the abdominal route is the rational operation

Collective Suggestion in Insane Asylums—Repond believes that the various excentric manifestations of negativism in schizophrenic patients are chiefly, if not exclusively provoked and kept up by the opposition of the patient to injurious surroundings and by insufficient psychologic treatment The unpleasant general conditions of the asylum are not apt to awaken the taste for reality in these patients, who find in their autism a comfortable escape from such surroundings Criminal insane inmates easily infect the whole institution An incompetent nurse may in a few days, create a generally hostile atmosphere Suggestion from the outside is another factor which favors entertainment of the collective suggestion that is unfavorable to treatment The asylums must be transformed into real hospitals with pleasant exteriors and interiors Wards should never contain more than fifteen patients The criminal psychopaths should be kept in special institutions, and the physicians should have more authority

Barbital—Schwartz's patient, a woman 81 years of age, took 150 Gm of barbital within eighteen months because of neurasthenia provoked by a cataract After that the cataract was extracted and the patient slept well without any craving for the drug

The Blood After Injection of Water.—Wollheim and Brandt injected intravenously 10 cc. of distilled water or of a 0.2 per cent solution of dextrose. Except in grave cases of contracted kidneys, the blood became diluted in from one to two hours, the chlorides of the serum increased and the amount of circulating blood decreased by from 20 to 40 per cent (trypan red method). Normal blood pressure did not change, while increased blood pressure fell by from 20 to 40 mm. of mercury. These changes are similar to those following venesection. They observed permanent lowering of the blood pressure in four out of thirteen patients with essential hypertension and in two out of six patients with nephritis. The injections were given four times a week for from three to six weeks.

Intracutaneous Injections Against Pain.—Falinski injected 1 cc. of an iso-ionic solution (resembling Ringer's) intracutaneously at five points at least 2 cm. apart (0.2 cc. in each). The injections were repeated after from three to four days. He observed alleviation or disappearance of various pains in 90 per cent of his patients (neuralgia, ulcer of the duodenum, neurosis of the heart and myalgia).

Pituitary Extracts in Cholelithiasis.—Garrè does not believe that it is possible to drive out a calculus from the gallbladder or cystic duct by injecting pituitary extract.

Surgery of Pituitary Tumors.—Krause decidedly prefers surgery to roentgen-ray treatment of tumors of the pituitary gland, especially because it is still uncertain whether the roentgen rays may not injure the chiasma. Decompression acts favorably upon all symptoms. He mentions a case in which a severe arterial bleeding compelled him to discontinue the operation after having merely cut into the capsule of the tumor. In spite of this, the patient's vision improved and the acromegalic symptoms and the impotence disappeared.

Surgery of Recurrence of Brain Tumor.—Schmieden and Peiper maintain that recurrent cerebral tumors should be extirpated, repeatedly if necessary.

Dangers and Difficulties of Operations on Brain Tumors.—Brain surgery does not present particular dangers as regards hemorrhage or infection, Hildebrand asserts, and the anesthetic risk can be greatly reduced by using local anesthesia, especially since anesthesia is needed only for the operation on the skull. The permanent results from operations on brain tumors are not, however, cheering. Neither gliomas nor sarcomas (whether the latter arise from the meninges or from the brain itself) can be removed without grave danger of recurrence. Roentgenotherapy after exposure is the best treatment. Peritheliomas or endotheliomas offer better prospects. A glioma situated in a ventricle (a very rare location) is circumscribed and may be removed entire, but in this case the primary danger of the operation is great. Fatal collapse not infrequently follows operation on tumors of the cerebellopontile angle, without a clear cause being assignable. The collapse is probably due to changes in intracerebral pressure, failure of the blood supply to the medulla oblongata or interference with the respiratory center. Attempts to remove these tumors, as also the more or less pedunculated or free tumors of the cerebellum should be made, in spite of the dangers of the operation. Hildebrand has operated on twelve cerebellopontile angle tumors, with 50 per cent mortality.

Encephalitis and Its Consequences.—Tilman believes that trephining should be done as early as possible in all acute cases, both to cut short the disease and to prevent sequelae. He reports briefly ten cases of encephalitis, in four of which postencephalitic epilepsy or paresis, of from seven to seventeen years' standing, was cured or improved by operation. He has observed that the disease is more likely to occasion epileptic symptoms when the focus is near the cortex. In deep seated processes, there is danger of perforation into the ventricle.

Skull Injury from Electric Current.—The case described by Ranzi, Mayr and Oberhammer is that of a man injured by an electric current while at work in an electric locomotive. The current entered the body above the right ear and passed out at the vertex, a little to the left. He was removed unconscious, but had recovered consciousness at the end of seven hours. The wounds were treated conservatively. In each the skin necrosis progressed and the bone became exposed. A month after the injury, epileptic attacks set in with paresis of the right side of the face and the right upper extremity. Four operations were performed, at which epidural, subdural and brain abscesses were opened and the diseased bone cleaned away. Streptococci and pneumococci were found in the pus from the abscesses in the brain. The patient died two months after the injury. On microscopic examination the bone showed rarefying, sequestrating osteomyelitis, the necrosis limited by granulating inflammation. The authors suppose that the electric current killed bone cells, which thus became a fit field for infection by extension from the suppurating soft parts. They advise active treatment, with early trephination in cases in which the bone necrosis progresses rapidly and intracranial complications are to be feared.

Surgery of Pruritus.—Total extirpation of the diseased region was performed successfully by Kuttner in two cases in which the pruritus was confined to the prepuce. Others have applied the principle to pruritus ani and pruritus vulvae with good results. Interruption of nerve conduction by injection of sodium chloride or of a local anesthetic by incisions designed to lift the skin from the subcutaneous tissue, by nerve section (personal case, pruritus auricularis, described and illustrated) and by resection of the nerve root is discussed. The literature contains a number of observations of operation on the sympathetic for relief of pruritus, but periarterial sympathectomy seems to have been tried only once, and then without sucess.

Experimental Denervation of the Heart.—In three dogs, the cardiac nerves together with the stellate ganglion were excised close to the heart. It appeared from the experiment that the extracardiac innervation of the heart is more extensive than the macroscopically visible nerves would lead one to suppose. At the end of a year, an extracardiac influence on the heart (other than by the body fluids) could be demonstrated. While cardiac insufficiency was not observable when the animals were at rest, it was apparent when they ran. Thyroidin was without influence on the denervated dogs, while in control animals it caused tachycardia. Two normal dogs fed on thyroidin died with emaciation, while the denervated dogs remained well.

Treatment of Bronchiectasis.—On a girl, aged 16, who had bronchiectasis of the lower lobe of the left lung, and in whom internal treatment had failed, Zaaijer first performed rib resection with removal of the periosteum and the intercostal musculature. The result was unsatisfactory. Exeresis of the phrenic nerve was then done, but without success. His next procedure was to expose the diseased lower lobe, free it from all attachments except at the hilus and isolate it with tampons ready for extirpation or resection at a later sitting. To his surprise, another operation was not necessary, the expectoration stopped entirely and permanently after fourteen days. Tamponade was continued, the lobe became smaller and smaller, the cavity diminished in size and the skin margins drew ever nearer to the deepest point of the cavity. A roentgenogram shows the lower lobe completely obliterated, and the upper containing air. Clinically the patient is entirely cured. Zaaijer proposes the following sequence of operations for lower lobe bronchiectasis, after any one of them cure may result, furthermore, each one lessens the danger of the following procedure: 1. Exeresis of the phrenic nerve. 2. Extensive rib resection over the disease focus, with removal of the periosteum and intercostal musculature. 3. Intrathoracic isolation of the diseased lobe by tamponade. 4. Incision, resection or extirpation of the diseased lobe.

Experimental Researches on the Origin of Pulmonary Emphysema.—Tracheal stenosis from tumor was imitated in animals by plugs of paraffin or wax introduced into the upper mediastinal space. This was followed by dyspnea on inspiration, so-called stenotic breathing. The changes caused by long continued breathing of this type were studied by Nissen and found to correspond to those of alveolar emphysema and true interstitial emphysema. Rigid enlargement of the thoracic space, from operation on the thoracic walls, did not lead to pulmonary emphysema. The results of the experiment thus spoke against the thoracogenic theory of the origin of emphysema. In animals in which large areas of the lung were excluded from function, a true interstitial emphysema developed in the functioning tissue after a considerable time. This compensatory emphysema is a consequence of chronically deepened breathing.

Operative Treatment of Gastric and Duodenal Ulcers.—Haberer finds that surgeons are no nearer than ever to unanimity on this question. He notes a recent tendency to conservatism on the part of some, notably, Bier, Kuttner and Payr. The late results of gastro-enterostomy cannot, however, be satisfactory, although it is the best of the indirect methods from the standpoint of occurrence of jejunal ulcer, and it has its place, especially in the hands of the inexperienced surgeon when working under difficulties on a patient in a critical condition. Pyloric exclusion should be abandoned, it does not accomplish any more than does gastro-enterostomy and it is followed by jejunal ulcer in a much higher percentage of cases. Haberer has had no personal experience with Balfour's cauterization or with Kraske's transgastric excision of the ulcer, but he does not consider them of value. Radical operation must remove the antrum and the pylorus. He does not recommend carrying the resection further toward the cardia. By antrum he means all that portion of the stomach which contains pyloric glands. The extent of the antrum varies in different stomachs. Resection of the lesser curvature, carried to the point where the trunk of the arteria gastrica sinistra approaches the stomach wall from the lesser omentum, should include it. The only correct treatment of jejunal ulcer is its radical resection. In chronically recurring hemorrhage from ulcer, operation should be performed before anemia has caused irreparable harm. In acute hemorrhage, conservative treatment is safer, unless ulcer has previously been diagnosed with certainty. Perforation should be operated on without delay. In covered perforation treatment should be expectant until the symptoms have receded.

Operative Prospects of Cholelithiasis.—Anschutz's statistics indicate that older persons can be operated on for gallstones without great danger, if the operation is done in the interval, i. e., when neither icterus nor fever is present. The dangers of the operation lie not so much in the age of the patient or the long standing of the disease as in retention of bile and acute infection. His mortality statistics for the interval operation show that the sharp rise attributable to age does not set in until the sixtieth year, twenty years later than would appear from the general statistics for gallstone operations. In operation during the attack, the danger increases greatly with age. The new internal methods of treatment should be studied by the surgeon, for use before and after operation. He believes them particularly useful in treatment of postoperative recurrence. The advances in functional and roentgenologic diagnosis are of great promise.

Primary Chronic Appendicitis.—Payr discusses at length this disease, the existence of which is in dispute. For his own part, and speaking strictly from a clinical standpoint, he regards stasis of the contents of the proximal portion of the large intestine (from enteroptosis, kinking or adhesions) with widening of the lumen and slight, superficial inflammatory changes in the mucous membrane of the appendix as evidence of chronic inflammation; he does not see the necessity of assuming previous severe bacterial infection in the crypts. Because of the absence of a typical anamnesis and of a uniform clinical picture, the diagnosis is often confused—hence the 40 per cent of cases in which appendectomy did not bring relief. The roentgen ray is a valuable aid in diagnosis. (Four pictures are reproduced.) The blood picture should be studied. Where the diagnosis lies between chronic appendicitis and ptosis, treatment appropriate to the latter should solve the problem. Massage and athletics may be used as provocatives to clarify the diagnosis. Surgeons are disagreed as to the advisability of operation. Payr holds to the middle path, but counsels that every diagnostic means be exhausted before resorting to surgery. The advisability of removing the appendix on the occasion of other operations is discussed. Here, also, Payr avoids extreme views.

The Origin of Acute Appendicitis.—Ritter believes that in typical acute appendicitis gangrene precedes suppuration, that the latter is nature's effort to get rid of the dead tissue. He sees the origin of the gangrene in a defect of the mucous membrane caused by the friction of a fecal concretion, which has, perhaps, disappeared. Whether the next step in the process is the work of toxins or of bacteria, is uncertain; the latter seems more probable to Ritter.

Treatment of Hypertrophy of the Prostate with Injection of Animal Blood and Roentgen Rays.—Hintze describes the conservative treatment of aged patients with hypertrophied prostate in use in Bier's clinic. Series of roentgen-ray treatments are given, and between the first and second of each series 5 cc. (reduced to 3 or 2 cc. when the series is repeated) of ox, hog or sheep blood is injected slowly into the prostate, half of the dose into each half of the organ. The patient is in the lithotomy position during the injection and is afterward put to bed. The resulting pain is usually not great. The irradiations are given at two or three day intervals and number about eight. On each occasion two fields are exposed, a transverse field above the symphysis and a perineal field (hard filter, diameter of field 10 by 15 cc., focal distance 30 cm.), in case of vesical fistula above the symphysis, a vertical field, 6 by 8 cc., on each side of the median line, is irradiated. For each field the dose applied to the skin is 0.1 of the erythema dose. On the first sitting of the series the dose is doubled. In most cases, not more than three series are required. Nineteen cases are reported. Spontaneous micturition was achieved in all but three patients; these three had accustomed themselves to self-catheterization and could not be persuaded to give up the habit.

Influence of Diet on the Buffer Capacity of the Blood and on the Healing and Bacterial Content of Granulating Wounds.—This article, to which Sauerbruch contributes an introduction, represents researches carried on in the surgical clinic at Munich over a period of several years. The modern conception of acidosis and the physiologic regulation of the p_H of the blood are discussed and clinical experiments with diets are described. Herrmannsdorfer found that the acid-base metabolism of patients with wounds differs from that of healthy persons. Both locally, at the seat of inflammation, and in the blood and other body juices the reaction is displaced toward the alkaline side. The alkali reserve, however and therewith the buffer capacity of the blood, is lowered in wound healing. The buffer substances in the blood are diminished more in the case of suppurative than of aseptic wounds, the lowest values, however, are found after the infection has been overcome. It is evident that general, "compensated" acidosis and local, true acidosis should be looked upon as measures of defense and not as dangerous phenomena of intoxication. An acid diet lowers the buffer capacity of the blood and the p_H of the urine, of the wound secretion and of the saliva. An alkaline diet has the opposite effect. In patients on an alkaline diet, the conditions in the wound became worse, the suppurative processes extended and there were flare-ups in old foci. The secretion increased and the wound showed no tendency to diminish in size. With an acid diet the wound became smaller, the secretion diminished or ceased, the granulations took on a healthy appearance. With an alkaline diet the bacteria increased in number and variety. Besides streptococci and staphylococci, *B. proteus*, *B. pyocyaneus*, pseudodiphtheria bacilli, anaerobes, spore-bearing bacteria and *Sarcinae* were abundant. In the wounds of patients on an acid diet, the number and variety of bacteria decreased greatly; bacteria disappeared from the circulating blood of two gravely septic patients when the latter were placed on an acid diet.

Lead Poisoning from Retained Projectile.—Habs quotes two cases in which a splintered projectile or a bullet, remaining in the body, gave rise to lead poisoning years later. The first case was from the Franco-Prussian war; forty years intervened between the entrance of the lead into the body and the appearance of symptoms. The second case dated from the late war, and Habs notes that lead poisoning from bullets received during this war are now becoming due and should be watched for by the physician. The literature is reviewed for similar cases and the chemical, pathologic and biologic aspects are considered. Internal remedies are of no use until the lead has been removed. Thereafter, potassium iodide is recommended.

Active Substances in Muscle.—Embden finds that lactacidogen, which is identified now as hexosemonophosphoric acid, is split suddenly in the beginning of a muscular contraction. Since it is more dissociated than phosphoric acid, the hydrogen ion concentration decreases after the cleavage. A further increase in alkalinity is due to a simultaneous splitting of adenosin-phosphoric acid into ammonia and inosinic acid. Both substances are resynthetized, unless the muscle is overworked. The production of lactic acid occurs after the contraction and counteracts the alkalinity produced by the two processes mentioned above. It also enhances the restitution of lactacidogen. Embden believes that the lowered hydrogen ion concentration causes the contraction of the muscle. This is an exothermic physical process and is followed by chemical processes which recharge the muscle with energy. He intends to look in the nervous system for nucleotids as substratums of the excitation process

Insulin-Thyroid Antagonism.—Rosenberg found that insulin does not markedly counteract a glycosuria induced by administration of thyroid or by exophthalmic goiter The point of attack of both substances is apparently different Nevertheless it is possible, by administration of thyroid to a diabetic patient, to provoke a glycosuria which can be controlled by insulin.

Peripheral Action of Epinephrine.—Freudenberg shows that intramuscular injection of epinephrine enhances locally the tetany provoked by hyperpnea and administration of sodium bicarbonate.

Alleged Cataract from Avitaminosis.—Goldschmidt repeated with Yoshimoto the experiments made by Szily and Eckstein. Differing from these authors, he believes that the cataract found in the rats is due solely to exposure of the eyes of the rats to a lower temperature. It disappears when the litter is warmed by the mother rat. The diet only prolongs the period during which this phenomenon can be produced in young rats.

Photosensitized Striated Muscle.—Lippay observed twitching and contracture of photosensitized muscles on exposure to light Hematoporphyrin produced a stronger sensitization than any of the other substances that he used. Muscles thus sensitized contracted even in diffuse daylight.

Endothelial Cells in Sepsis.—Hammerschmidt isolated a strain of bacilli that is extremely virulent for mice. It causes scarcely any macroscopic changes, but all the endothelial cells of the blood vessels and the Kupffer cells are crammed with the bacilli

Synthalin.—Morawitz observed only a few therapeutic failures with synthalin. Nevertheless he acquired the impression that it may injure the liver Urobilinuria appears frequently. Besides this, the blood sugar level does not fall as easily as with insulin. He confirms the fact that the digestive disturbances from synthalin may be counteracted by simultaneous administration of biliary salts.

Antimalarial Action of Quinine.—Giemsa believes that quinine is absorbed by the endothelial cells and transmitted by them to the parasites.

Duodenal Tubage in Typhoid.—Henning and Lechner found the bacilli in the bile in nineteen out of thirty-six typhoid and paratyphoid B patients. The method has no practical advantage over other bacteriologic methods.

Dangers of Hysterography.—Hellmuth's patient died from diffuse peritonitis after intra-uterine injection of 3 cc. of a contrast fluid for the purpose of hysterography. There had been no sign of suppuration of the tubes, which would have served as a timely warning against the injection.

Protein Injection and Innervation of the Stomach.—Müller and Petersen found that the stomach dilates and its movement ceases during the chill following an intravenous injection of a vaccine, peptone or protein. External application of cold, which also produces a chill, causes the same disturbance of the stomach. Periarterial sympathectomy made on the extremity exposed to the cold prevents this reflex. If the toxicity of the injected substances is great, the secretion of the stomach increases ten to twenty times, simultaneously with the dilatation, but does not necessarily contain any hydrochloric acid. Nausea and vomiting are common in this stage. This reaction is most pronounced after injections of a typhoid and colon bacillus vaccine or of living colon bacilli. They point out that the protein shock acts on the stomach indirectly by way of the nervous system. The action of foreign proteins occurs after their penetration into the tissues, in which they provoke a reaction. The reaction of the vegetative nervous system sometimes lasts longer than the cellular reaction. In the treatment of gastric ulcer, only an intramuscular injection of almost indifferent proteins (milk) should be used, which is sufficient for relaxation of the tonus. With more potent proteins and vaccines, and other ways of injection, the secretion of the stomach would increase. The action of the liver is also stimulated in the latter case and the temperature of the body rises, because the opposite reflex (vasoconstriction) occurs in the skin and prevents dissipation of the excess heat.

*"Christmas Fever." Stappert, Jr.—p. 642.

Constitution and Tuberculosis.—Naegeli declares that there unquestionably exists a difference in virulence in different strains of the human type of the tubercle bacillus. The outcome is decided by the constitutional differences of the patient. Exogenic conditional factors are most important, but genotypic characters also play a rôle. Since practically everybody becomes infected with tuberculosis, he believes that it would be better to speak of a predisposition to lethal tuberculosis than of a predisposition to tuberculosis in general.

Specific Adsorption Treatment.—Bechhold and Keiner discuss the purpose of adsorption treatment. Bechhold suggested distinguishing between the adsorption capacity (for dissolved substances) and the adhesion capacity (for corpuscular elements, such as bacteria). The ideal adsorbent should have a great power of adhesion and a selective power to adsorb toxic substances, but not digestive enzymes. They tested some combinations, which gave encouraging results.

"Christmas Fever."—Stappert uses this term for the numerous cases of malingering around the Christmas holidays. Since the social insurance premium is paid regardless of holidays, the malingerer receives as much money as if he were working.

Diseases of the Tonsils in Children.—Hamburger points out that in inflammations of the pharyngeal tonsil the swollen lymph nodes are localized farther back (underneath the sternocleidomastoid) than in ordinary tonsillitis. Diphtheria should be assumed with a bloody purulent discharge from the nose, and is practically certain if there are also white spots in the pharynx. A tonsillitis plus hoarse voice suggests laryngeal diphtheria and should be treated accordingly, regardless of the results of a bacteriologic examination. An open mouth and oblique position of the head suggest pharyngeal abscess. It is well to delay, in the incision of a tonsillar abscess, unless the pus may be seen underneath the surface. He would not torture a child with tonsillitis by wiping off the tonsils. Such a procedure is only to be recommended, if coughing persists after whooping cough.

Toxins of Sepsis Streptococci.—Herrmann and Heidler had good results in treatment of sepsis with antitoxic serums obtained by a method similar to Dick's.

Campaign Against Cancer in Jugo-Slavia. J. Cholewa.—p. 604.

Heterotransplantation of Malignant Tumors.—Roskin obtained growth of chicken sarcoma in mice that had been injected with ferrum oxidatum saccharatum. A piece of this tissue taken on the sixtieth day, and regrafted into fowls produced a sarcoma, but of a somewhat slower growth. Heterogenetic transplantation of adenocarcinoma of mouse or man into fowls induced the formation of tumors that resembled lymphosarcoma.

Action of High Oxygen Pressure on Mouse Cancer.—Fischer, Buch Andersen, Demuth and Laser kept cancer mice for twenty-two hours in oxygen under a pressure of 1.6 atmospheres or for fourteen hours under 2 atmospheres. Certain of the animals were injected besides with various preparations intended to act as catalyzers of oxidation. Some of the animals were cured by the oxygen alone, but the results were considerably improved by the combined treatment (around 20 per cent improvement). They emphasize the fact that it is a long way from these experiments to attempts to influence cancer in man.

Cancer Treatment as Physico-Chemical Problem.—Buch Andersen and Fischer discuss the physical and chemical aspects of cancer therapy, especially with oxygen. They mention similar theoretic possibilities with other gases, especially hydrogen.

Natural Immunity to Rous Sarcoma.—Fischer found that Rous chicken sarcoma may be cultivated in the plasma from naturally immune chickens or from birds or rabbits that have been immunized. All these immune serums inhibit in vitro the effect of the filtrable agent of Rous sarcoma. The plasma of about 40 per cent of chickens has this property normally. The transplanted sarcoma takes in such animals only if its cells are not destroyed. This shows that humoral immunity alone is not sufficient to prevent the growth. About 1 per cent of the chickens are, apparently, absolutely immune—against the filtrable agent of the sarcoma as well as against the cells.

*Method for Treatment of Ischuria. E. I. Kvater.—p. 117.

New Method of Treating Postoperative or Postpartum Retention of Urine.—Kvater suggests a method which he has used for the last two years in cases of retention of urine, after operation or childbirth. The desire for micturition is absent, although the amount of the urine in the bladder is large. This condition is due to atony of the detrusor urinae muscle associated with spasm of the sphincter vesicae. The treatment is based on the theory that increase of intravesical pressure may cause the bladder to contract. The method is as follows: when the retention of the urine has persisted for twelve hours, the bladder is catheterized and a disinfecting liquid is introduced. The quantity of the liquid must exceed by from 150 to 200 cc. that of the urine removed. The liquid is usually spontaneously expelled, and normal micturition then takes place. If the first injection remains without effect, from 60 to 100 cc. more of the liquid is introduced. Rupture of the bladder did not occur in any case. The method succeeded in cases in which other measures failed.

*Resistance of Erythrocytes to Quinine. A. Voinik.—p. 20.

Lytic Action of Quinine on Erythrocytes in Malaria.—Voinik refers to his previous researches, showing that the favorable action of quinine in malaria consists in dissolution of the damaged erythrocytes and consequent falling off of the plasmodia. The plasmodia are then destroyed by the corresponding lysins of the blood serum. He further studied the influence of various substances and conditions on the hemolytic property of quinine. Test tubes were filled with a 0.5 per cent solution of sodium chloride mixed with quinine hydrochloride, in various concentrations. A drop of the blood to be examined was added to the tubes. There was evidence that in normal conditions the erythrocytes of children are less resistant to the action of quinine than are those of adults. In malaria the hemolytic action of quinine is in inverse proportion to the content of sodium chloride in the blood. Rise of temperature increases the hemolysis, thus justifying the administration of quinine three or four hours before the expected paroxysm of malaria; alcohol and ammonia enhance the hemolysis considerably. Stress is laid on the fact that in treatment of malaria the amount of sodium chloride in the blood should be taken into consideration.

Scarlet Fever Streptococci Isolated in the Epidemic of 1925-1926. E. Korobkova and S. Mitin.—p. 19.
*Influence of Cytotoxic Serum on Development of Cancer. A. Bogomolets and I. Neiman.—p. 33.
Note on Experimental Gonorrhea. Z. Osipova and A. Ukhin.—p. 86.

Stimulating or Blocking the Reticulo-Endothelial System and Its Effect on Development of Cancer.—Bogomolets and Neiman inoculated 342 mice with an emulsion of adenocarcinoma. A series of these animals were injected simultaneously with cytotoxic rabbit serum, another series with ordinary rabbit serum. The controls were inoculated only with the emulsion. Large doses of any of the serums were found to favor the development of cancer, probably by paralyzing the active macrophages in the connective tissue. Small doses of serum stimulated the resistance of the connective tissue, reducing markedly the percentage of tumors that developed in the animals. The prophylactic action of the ordinary serum was much weaker than that of the cytotoxic serum. The "cancer diathesis" consists in reduced defense of the organism against the disease, determined by the condition of the connective tissue. Researches are being carried on to test the curative action of the cytotoxic serum, also to establish the histologic changes induced by the serum in the mesenchyma.

Clinical Results with Synthalin. B. Sybrandy.—p. 1418.
*Bleeding Nipple. J. G. Kopp.—p. 1431.
*Swine Erisipelas in Man. C. Schaap.—p. 1447.
*Bilateral Absence of the Thumb. A. J. P. van den Broek.—p. 1452.

Bleeding Nipple.—Kopp analyzes twenty-two cases of bleeding nipple. Pathologic examination was made in twenty, and showed that in nine the cause was intracanalicular papilloma, in nine others chronic cystic mastitis, in one a combination of the two, and in one precarcinoma. In sixteen the secretion from the nipple was the only symptom. In nearly all it resembled venous blood in appearance; in some the discharge had at first been serous, and had gradually become bloody. He does not approve of conservative treatment, but he does not believe that the typical radical operation, as for carcinoma, is necessary, unless, of course, carcinoma is suspected. In younger women, if swelling is absent, he exposes the posterior surface of the mammary gland by a latero-inferior incision, and, according to the information obtained by inspection and palpation, performs either partial extirpation or subcutaneous enucleation of the gland. In older patients, he advises removal of the entire breast.

Swine Erysipelas in Man.—Schaap has had three cases of swine erysipelas in human beings in the last two years. In all the infection could be traced to the slaughtering of a sick hog. The animal responsible for the last two cases had been sick only one day, and was thus in the prodromal stage. In all three cases cure was effected by serum from animals with the disease. In one patient, in whom the disease had reached the generalized stage, 40 cc. was injected; in the other two, treated earlier, 20 cc.

Bilateral Absence of the Thumb.—In the case here reported, there were no signs that even a rudimentary thumb had ever existed on either hand. Otherwise, the skeleton did not present any congenital abnormalities. The subject, a girl, aged 23, is able to do all kinds of housework, writing and sewing as well and as rapidly as persons with normal hands.

*Chemical Warfare. H. Westermark.—p. 273.
*Strumectomy. A. Troell.—p. 290.
A Statistical and Serologic Study of Cancer. L. Wolff.—p. 312.

The Most Important War-Gases and the Diseases Caused by Them.—After a short historical outline Westermark divides the gases into different groups, each of which causes its special disease with characteristic symptomatology and anatomic pathology and demands its own treatment The two most important are the lung-irritating and the blister-causing gases To the first group belong chlorine, chlorpicrine and phosgene They cause edema of the lung The hemoglobin may be increased to more than 120, the red blood cells to over 9,000 000 To prevent the pulmonary edema emetine chloride should be given subcutaneously Stimulants, such as caffein and camphor are indicated The next group is the vesicant To this belong mustard gas and "Lewisite" The first was used during the World War The last has not yet been employed in war Mustard gas is very poisonous, even in small amounts and cannot be detected by the sense of smell It easily penetrates ordinary cloth The pathologic-anatomical changes are many 'Lewisite" is a heavy oily fluid It is resistant A fatal dose on the skin is 1 5 cc it causes burns and arsenic poisoning As a remedy benzyl alcohol, 100 Gm , ethyl alcohol 95 Gm, and glycerin, 4 Gm, is recommended

Strumectomy—Troell reviews his total material of 337 cases Of these, 193 were clinically toxic and 144 atoxic The mean value of the basal metabolic rate on admission of the patient to the hospital was in cases of diffuse exophthalmic goiter approximately + 55 per cent, the corresponding figure for adenomatous toxic goiter was + 34 per cent Of patients with diffuse exophthalmic goiter in whom the basal metabolic rate was determined it was + 50 per cent on admission in forty five more than 50 in forty nine in thirty-one cases it was not determined before operation By treatment with Lugol's solution insulin or bromium-quinine-phosphorus calcium, and rest in bed it was considerably reduced before the operation was undertaken None of the cases with a basal metabolic rate of + 30 per cent or less, died from the operation Of the patients with toxic goiters about 85 per cent recovered completely after the operation In patients with diffuse goiter preoperational treatment with Lugol's solution is valuable for temporarily reducing the thyrotoxicosis Should rest in bed in a hospital and treatment with Lugol's solution, controlled by determinations of the basal metabolism and weighing not result in improvement in the basal metabolic rate, body weight, tachycardia, etc , in, at the most four weeks, the case is probably so highly toxic as to exclude the possibility of a good result from thyroidectomy

Suspension Stability of the Blood in Tuberculosis of the Lungs O Stub —p 233
*Tuberculosis of the Knee Joint R Ingebrigtsen —p 271
*Influence of Malaria on Gonorrhea J Cammermeyer —p 280
*Cholelithiasis F Roscher —p 281

Mobilization of Tuberculous Ankylosis of the Knee Joint.—The patient was a woman, aged 21 Both knee joints were bent at a right angle, in the right there was bony ankylosis, in the left fibrous ankylosis The right ankle was stiffened at an acute angle She could move only on crutches The angulation of the right extremity was corrected by resection the right foot was placed in correct position by astragalectomy and the ankle joint was given normal mobility The left knee was mobilized, the fibrous deformities and a thin section from the articular cartilage were removed and the articular surfaces placed in correct position and covered with free fascia lata The result was good The patient can walk with a cane No complications have occurred in three years In the literature eight cases of attempted mobilization of a knee joint, ankylosed in the course of tuberculosis, are reported, with good results in six Ingebrigtsen thinks that mobilization is indicated if one or both joints are ankylosed in flexion, if the tuberculous process has stopped and the general health of the patient is good

Influence of Malaria on Gonorrhea—Cammermeyer assumes that the influence of malaria upon gonorrhea is only temporary and that it is not a specific remedy for gonorrhea, its occasional temporary influence is attributable to the height of the fever

Two Cases of Multiple Gallstones—Case 1 was in a woman, aged 47 Six years ago she began to feel pains under the right breast Epigastralgia followed During the following year she felt well, but had to be on a diet Aug 30 1926, she had an attack of severe pain This recurred on September 21, and three large stones were found in the feces On the following days several stones appeared in the stool and on October 14 sixty-two stones were found The total number was 190 On October 20 the gallbladder was removed, it was as large as a goose egg and contained about 100 stones and some normal bile The cystic duct was wide open The hepatic duct was also open, it did not contain stones Case 2 was in a woman, aged 43 This patient had had indigestion for about ten years In October, 1926 she suffered from severe pains in the epigastrium On October 19 thirteen stones of different sizes were found in the feces and on the 27th of the same month forty six stones The urine did not contain bile or albumin The patient has been well since and there has not been a recurrence of gallstones in the stool

Injury by Electricity J Ieg —p 339
Chronic Encephalitis H I Schou —p 343
The Quantity of the Excreted Urine E Faber —p 351
Problems of Social Medicine J Kuhn —p 355

Fermentative Dyspepsia and Its Chemical Picture.—Gram carried out a series of investigations, but these do not give any positive answer as to the etiology and the pathogenesis of fermentative dyspepsia A rational dietetic treatment effects, as a rule, considerable improvement and often apparent recovery Medical treatment plays only a secondary part All starches should at first be forbidden, after a time they may gradually be added to the diet If there is diarrhea tannalbin or bismuthsubsalicylate should be given, if constipation, liquid petroleum and oil enemas

Treatment of Diabetes with Synthalin—Lorenzen is of the opinion that in its present form synthalin cannot be recommended, as the effect of the doses that can be given is too slight and the inconveniences are greater than the advantages In mild cases, that can be treated by diet alone, synthalin is not needed and in severe cases it cannot replace insulin

RICKETS

A BRIEF SUMMARY, WITH REFLECTIONS *

HENRY J. GERSTENBERGER, M.D.
CLEVELAND

The course followed by the ship of pediatrics is changing. In many schools of medicine pediatrics now ranks with internal medicine, surgery and obstetrics as a major subject of instruction; in other words, it is no longer a so-called minor specialty.

The fact that pediatrics is receiving more and more consideration in the curriculum of the schools of medicine indicates clearly that its progress and importance are being appreciated and utilized. And the marked and rapid increase in the number of men devoting themselves to this field also shows that the public appreciates the value and need of pediatrics.

Physicians trained in pediatrics today are general practitioners of the best type, rather than specialists in the narrow sense, as they formerly were. In addition to caring for the physical ills of infants and children, the pediatrician of today is also concerned with the proper training of the child and with the prevention of disease. No field in medicine offers greater opportunities for the useful and effective application of preventive medicine, a statement today accepted as sound both by the public and by the government, whether it be local, state or federal.

But the question of the present and future responsibilities and opportunities of pediatrics has been so recently and so admirably discussed by former chairmen of this section, among them Veeder, Helmholz and Huenekens, that there is no need of my proceeding further in this direction. Therefore, I have chosen another topic for the subject of my address, namely, rickets, whose consideration, however brief, I hope will be of interest and of value.

Since Kurt Huldschinsky brought forth his fundamental and epoch-making proof of the antirachitic effectiveness of the ultraviolet rays, much has been added to our knowledge of this disorder during the last eight years by the work of many men, such as McCollum, A. F. Hess, Howland, Shipley, Park, Kramer, Czerny, Móro, Freudenberg, György, Adam, Mellenby and Findlay. And yet, in many respects, rickets is still a mystery. Nevertheless, in my opinion, sufficient progress has been made to make its prevention more intelligent and effective than it heretofore has been.
